Abstract

We use numerical methods to study the short term behaviour of the Serre equations in the presence of steep gradients because there are no known analytical solutions for these problems. In keeping with the literature we study a class of initial condition problems that are a smooth approximation to the initial conditions of the dam-break problem. This class of initial condition problems allow us to observe the behaviour of the Serre equations with varying steepness of the initial conditions. The numerical solutions of the Serre equations are justified by demonstrating that as the resolution increases they converge to a solution with little error in conservation of mass, momentum and energy independent of the numerical method. We observe and justify four different structures of the converged numerical solutions depending on the steepness of the initial conditions. Two of these structures were observed in the literature, with the other two not being commonly found in the literature. The numerical solutions are then used to assess how well the analytical solution of the shallow water wave equations captures the mean behaviour of the solution of the Serre equations for the dam-break problem. Lastly the numerical solutions are compared to asymptotic results in the literature to approximate the depth and location of the front of an undular bore.

Keywords: Serre equations, steep gradients, dam break

1. Introduction

The behaviour of flows containing steep gradients are important to a range of problems in shallow water such as the propagation of a bore, the dam-break problem and shoaling waves on a beach.

The Serre equations are used as a compromise between the non-dispersive shallow water wave equations and the incompressible inviscid Euler equations for modelling dispersive waves of the free surface in the presence of steep gradients, which are present for the Euler equations [1] but not for the shallow water wave equations. The

9 Serre equations like the shallow water wave equations produce methods [2–4] that are
10 computationally easier and quicker to solve than the best methods for the Euler equa-
11 tions. The Serre equations are considered the most appropriate approximation to the
12 Euler equations for modelling dispersive waves up to the shore line [5, 6]. Therefore,
13 understanding the behaviour of the Serre equations in the presence of steep gradients
14 offers some insight into the behaviour of steep gradients for fluids more generally.

15 There are no known analytical solutions to problems containing steep gradients for
16 the Serre equations. To infer the structure of solutions to problems containing steep
17 gradients in the near term we have to resort to investigating numerical solutions of the
18 Serre equations for these problems. Whereas utilising modulation theory the long term
19 behaviour of steep gradient flows for dispersive equations can be understood; with El
20 and Hoefer [7] providing a review of these results for dispersive shock waves.

21 There are few examples in the literature which depict the short term behaviour of
22 numerical solutions to the Serre equations in the presence of steep gradients [1–4, 8,
23 9]. These papers all present problems with discontinuous initial conditions [2–4] or a
24 smooth approximation to them when the numerical method requires some smoothness
25 of the solutions [1, 8, 9]. Among these papers there are differences in the structures
26 of the numerical solutions, with some demonstrating undulations in depth and velocity
27 throughout the bore [3, 4, 8] and others showing a constant depth and velocity state in
28 the middle of the bore [1, 2, 9].

29 The mean behaviour of numerical solutions to the dam-break problem for the Serre
30 equations is consistent across the literature [1–4, 8, 9] and was demonstrated to be well
31 approximated by the analytical solution to the dam-break problem by the shallow water
32 wave equations [2, 9].

33 Utilising modulation theory expressions for the long term leading wave amplitude
34 and speed of an undular bore for the Serre equations were derived and verified for a
35 range of undular bores by El et al. [8]. These expressions were also shown to be valid
36 for all the different structures found in the literature [8, 9].

37 The first aim of this paper is to investigate and explain why different short term be-
38 haviour has been published in the literature for numerical solutions of the Serre equa-
39 tions for problems containing steep gradients. We find that the undulations of a bore
40 can be damped to a constant depth and velocity state by the numerical diffusion in-
41 troduced by the method, as is the case for Le Métayer et al. [2]. Oscillation damping
42 can also occur due to the particular smoothing of the initial conditions, as is the case
43 for Mitsotakis et al. [1], El et al. [8] and Mitsotakis et al. [9]. Our results demon-
44 strate that in the short term our ‘growth’ structure is the correct structure for the Serre
45 equations for the dam-break problem. While over long time periods the Serre equa-
46 tions damps this “growth” structure, which is consistent with the expected long term
47 behaviour. However, this natural decay is dominated by other factors in the literature
48 for numerical solutions over short time spans.

49 The second aim of this paper is to assess the utility of the shallow water wave
50 equations as a guide for the evolution of an undular bore and compare our numerical
51 solutions with the Whitham modulation results of El et al. [8]. We find that for a range
52 of dam-break problems the analytical solution of the shallow water wave equations
53 is a good approximation for the mean depth and velocity of the Serre equations, as
54 is suggested by the numerical solutions of Le Métayer et al. [2] and Mitsotakis et al.

55 [9]. It was also found that the results of El et al. [8] are a good approximation to our
 56 numerical solutions. However, unlike the results of El et al. [8] and Mitsotakis et al.
 57 [9] we demonstrate that the Whitham modulation results can underestimate the leading
 58 wave height and speed in the near term, even when the bore height is below the critical
 59 value.

60 The first aim of this paper is achieved by demonstrating that our numerical solutions
 61 are good approximations to the true solutions of the Serre equations. This is accom-
 62 plished by demonstrating that as the resolution of a particular method is increased, the
 63 numerical solutions converge to a numerical solution with little error in the conserva-
 64 tion of mass, momentum and energy. The numerical solution is also consistent across
 65 the five different numerical methods. Three of the methods are the first, second and
 66 third-order methods presented by Zoppou et al. [4]. The first-order method is equiva-
 67 lent to the method of Le Métayer et al. [2]. The fourth method is a recreation of the
 68 second-order method used by El et al. [8]. Lastly, the fifth method is a second-order
 69 finite difference approximation to the Serre equations.

70 The second aim is accomplished by comparing our verified numerical solutions to
 71 the analytical solutions of the shallow water wave equations and the Whitham modula-
 72 tion results presented by El et al. [8].

73 The paper is organised as follows, in Section 2 the Serre equations and the quan-
 74 tities they conserve are presented. In Section 3 the smoothed dam-break problem is
 75 defined and the notation for the measures of the relative difference between numerical
 76 solutions and the relative error in the conserved quantities is introduced. The analytical
 77 solution of the shallow water wave equations and the expressions for the amplitude and
 78 speed of the leading wave of an undular bore are presented. In Section 4 the numerical
 79 methods and their important properties are presented. In Section 5 the four different
 80 structures in the solutions of smoothed dam-break problem for the Serre equations are
 81 determined using verified numerical solutions. The verified numerical solutions are
 82 also used to compare the analytical solution of the shallow water wave equations to the
 83 mean behaviour of the solution of the Serre equations for the dam-break problem. The
 84 Whitham modulations results are also compared to the verified numerical solutions.

85 2. Serre Equations

86 The Serre equations can be derived by integrating the full inviscid incompressible
 87 Euler equations over the water depth [10]. They can also be derived as an asymptotic
 88 expansion of the Euler equations [11]. Assuming a constant horizontal bed, the one-
 89 dimensional Serre equations are [12]

$$90 \quad \frac{\partial h}{\partial t} + \frac{\partial(uh)}{\partial x} = 0 \quad (1a)$$

92 and

$$93 \quad \underbrace{\frac{\partial(uh)}{\partial t} + \frac{\partial}{\partial x} \left(u^2 h + \frac{gh^2}{2} \right)}_{\text{Shallow Water Wave Equations}} + \underbrace{\frac{\partial}{\partial x} \left(\frac{h^3}{3} \left[\frac{\partial u}{\partial x} \frac{\partial u}{\partial x} - u \frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial x \partial t} \right] \right)}_{\text{Dispersion Terms}} = 0. \quad (1b)$$

94 Serre Equations

Where $u(x, t)$ is the horizontal velocity over the depth of water $h(x, t)$, g is the acceleration due to gravity, x is the horizontal spatial variable and t is time.

The Serre equations are conservation laws for ‘mass’ (1a), ‘momentum’ (1b) and the Hamiltonian [13, 14]

$$\mathcal{H}(x, t) = \frac{1}{2} \left(hu^2 + \frac{h^3}{3} \left(\frac{\partial u}{\partial x} \right)^2 + gh^2 \right) \quad (2)$$

which is the total energy.

3. Smoothed Dam Break Problem

In this section we define a class of initial condition problems, called the smoothed dam-break problem that we use throughout our numerical investigation. This class of initial conditions are used in the literature [1, 9] to smoothly approximate the discontinuous initial conditions of the dam-break problem, as some numerical methods require smoothness of the solutions.

The smoothed dam-break problem has the following initial conditions

$$h(x, 0) = h_0 + \frac{h_1 - h_0}{2} \left(1 + \tanh \left(\frac{x_0 - x}{\alpha} \right) \right) m, \quad (3a)$$

and

$$u(x, 0) = 0.0 \text{ m/s}. \quad (3b)$$

This represents a smooth transition centred around x_0 between a water depth of h_0 on the right which is smaller than the water depth of h_1 on the left. Here α measures the distance over which approximately 46% of that smooth transition between the two heights occurs. These are the same h_0 and h_1 values as those of the smoothed dam-break problem of El et al. [8] and the dam-break problem of Le Métayer et al. [2].

There are no known analytical solutions of the Serre equations for the dam-break problem or an arbitrary smoothed dam-break problem. Therefore, to demonstrate that our numerical solutions converge we use the relative difference between numerical solutions L_1^h and L_1^u for the primitive variables h and u respectively. To demonstrate that our numerical solutions conserve the quantities h , uh and \mathcal{H} well we use the relative error of their conservation C_1^h , C_1^{uh} and $C_1^{\mathcal{H}}$ respectively.

3.1. Background for derived and observed comparisons

It was demonstrated by Le Métayer et al. [2] and Mitsotakis et al. [9] that the analytical solution of the shallow water wave equations for the dam-break problem captures the mean behaviour of the numerical solutions of the Serre equations to the dam-break problem [2] and the smoothed dam-break problem [9].

El et al. [8] derived an expression for the long term amplitude of the leading wave of an undular bore A^+ for the Serre equations. Since the front of an undular bore decomposes into solitons, the speed of the leading wave S^+ can be calculated from its amplitude.

To be self contained we present the analytical solution of the shallow water wave equations to the dam-break problem and the expressions derived by El et al. [8].

Figure 1: Analytical solution at $t = 30s$ of the dam-break problem for the shallow water wave equations with $h_0 = 1m$, $h_1 = 1.8m$ and $x_0 = 500m$.

3.1.1. Shallow Water Wave Equation Analytical Solution

For the dam-break problem the shallow water wave equations, which are the Serre equations with dispersive terms neglected, can be solved analytically.

An example of the analytical solution of the shallow water wave equations for the dam-break problem is presented in Figure 1. Region I is the undisturbed water upstream of the dam-break at constant height (h_1) and velocity ($0m/s$). Region II is the rarefaction fan connecting regions I and III. Regions III and IV compose the constant height (h_2) and constant velocity (u_2) state, with the regions separated by $x_{u_2} = x_0 + u_2 t$. Region V is the undisturbed water downstream at constant height (h_0) and velocity ($0m/s$) separated from Region IV by a shock which travels at velocity S_2 . Expressions for the unknown quantities h_2 , u_2 and S_2 in terms of h_0 and h_1 were given by Wu et al. [15] as

$$h_2 = \frac{h_0}{2} \left(\sqrt{1 + 8 \left(\frac{2h_2}{h_2 - h_0} \frac{\sqrt{h_1} - \sqrt{h_2}}{\sqrt{h_0}} \right)^2} - 1 \right), \quad (4a)$$

$$u_2 = 2 \left(\sqrt{gh_1} - \sqrt{gh_2} \right) \quad (4b)$$

and

$$S_2 = \frac{h_2 u_2}{h_2 - h_0}. \quad (4c)$$

Applying (4) to our dam-break heights of interest; $h_0 = 1m$ and $h_1 = 1.8m$ results in $h_2 = 1.36898m$, $u_2 = 1.074975 m/s$, $S_2 = 3.98835 m/s$ and $x_{u_2} = 532.24925m$ which are shown in Figure 1 for $t = 30s$. The location of the front of the bore for the shallow water wave equations at time t is thus $x_{S_2} = x_0 + S_2 t$ so that $x_{S_2} = 619.6505m$ at $t = 30s$.

3.1.2. Whitham Modulation for Undular Bores of the Serre Equations

Utilizing Whitham modulation theory for a one-phase periodic travelling wave an asymptotic expression for the amplitude A^+ and speed S^+ of the leading wave was

164 derived by El et al. [8]. The derived expressions for A^+ and S^+ are

$$165 \quad \frac{\Delta}{(A^+ + 1)^{1/4}} - \left(\frac{3}{4 - \sqrt{A^+ + 1}} \right)^{21/10} \left(\frac{2}{1 + \sqrt{A^+ + 1}} \right)^{2/5} = 0 \quad (5a)$$

166 and

$$168 \quad S^+ = \sqrt{g(A^+ + 1)} \quad (5b)$$

169 where $\Delta = h_b/h_0$, and h_b is the height of the bore. The height of the bore created by the dam-break problem in (5a) used by El et al. [8] was

$$h_b = \frac{1}{4} \left(\sqrt{\frac{h_1}{h_0}} + 1 \right)^2.$$

170 For our dam-break heights of interest $h_0 = 1m$ and $h_1 = 1.8m$ we obtain $h_b =$
 171 $1.37082m$, $\Delta = 1.37082$, $A^+ = 1.73998m$ and $S^+ = 4.13148m/s$. The location of the
 172 leading wave of an undular bore at time t is then $x_{S^+} = x_0 + S^+t$ so that $x_{S^+} = 623.9444m$
 173 for $t = 30s$.

174 4. Numerical Methods

175 Five numerical schemes were used to investigate the behaviour of the Serre equa-
 176 tions in the presence of steep gradients, the first (\mathcal{V}_1), second (\mathcal{V}_2) and third-order
 177 (\mathcal{V}_3) finite difference finite volume methods of Zoppou et al. [4], the second-order fi-
 178 nite difference method of El et al. [8] (\mathcal{E}) and a second-order finite difference method
 179 (\mathcal{D}) that can be found in the Appendix.

180 The \mathcal{V}_i methods are stable under a Courant-Friederichs-Lewy (CFL) condition pre-
 181 sented by A. Harten [16]. The \mathcal{V}_i methods have demonstrated the appropriate order of
 182 convergence for smooth problems [4]. Furthermore, \mathcal{V}_2 and \mathcal{V}_3 have been validated
 183 against experimental data containing steep gradients [4]. The two methods \mathcal{D} and \mathcal{E}
 184 were found to be stable under the same CFL condition.

185 Generally, we found that \mathcal{V}_1 is the worst performing method due to its numeri-
 186 cal diffusion [4]. Of the high-order methods \mathcal{E} is the worst performing, introducing
 187 dispersive errors.

188 5. Numerical Results

189 We investigate the behaviour of the Serre equations in the presence of steep gradi-
 190 ents by numerically solving the smoothed dam-break problem while varying the steep-
 191 ness of the initial conditions. As $\Delta x \rightarrow 0$ our numerical solutions should represent
 192 a good approximation of the true solution of the Serre equations. If our numerical
 193 solutions to a smoothed dam-break problem converge to the same numerical solution
 194 with little error in conservation of mass, momentum and energy as $\Delta x \rightarrow 0$ for each
 195 method, then this numerical solution is considered an accurate approximate solution to
 196 that smoothed dam-break problem for the Serre equations.

197 This process validates our numerical solutions for the smoothed dam-break prob-
 198 lem, and thus validates our numerical methods to approximate the solution of the Serre
 199 equations in the presence of steep gradients, if it exists. With a validated model we can
 200 compare the numerical solution to the analytical solution of the shallow water wave
 201 equations for the dam-break problem and the results of El et al. [8].

202 Throughout most of this section we are interested in the numerical solution at $t =$
 203 $30s$ to the smoothed dam-break problem with $h_0 = 1m$, $h_1 = 1.8m$ and $x_0 = 500m$
 204 while allowing for different α values. All numerical methods used $\Delta t = 0.01\Delta x$ which
 205 is smaller than required by the CFL condition, ensuring stability of our schemes. The
 206 method \mathcal{V}_2 requires an input parameter to its slope limiter and this was chosen to be
 207 $\theta = 1.2$ [4]. The spatial domain was $[0m, 1000m]$ with the following Dirichlet boundary
 208 conditions, $u = 0m/s$ at both boundaries, $h = 1.8m$ on the left and $h = 1m$ on the right.

209 5.1. Observed Structures of the Numerical Solutions

210 We observe that there are four different structures for the converged to numerical
 211 solution depending on the chosen α . They are the ‘non-oscillatory’ structure \mathcal{S}_1 , the
 212 ‘flat’ structure \mathcal{S}_2 , the ‘node’ structure \mathcal{S}_3 and the ‘growth’ structure \mathcal{S}_4 . An example
 213 of each of these structures is shown in Figure 2 which were obtained using \mathcal{V}_3 with
 214 $\Delta x = 10/2^{11}m$.

215 The four structures are identified by the dominant features of the numerical solu-
 216 tions in regions III and IV. They also correspond to different structures in the numerical
 217 solutions that have been presented in the literature. From Figure 2 it can be seen that as
 218 α is decreased, steepening the initial conditions, the numerical solutions demonstrate
 219 an increase in the size and number of oscillations particularly around $x_{u_2} = x_0 + u_2t$. We
 220 observe that the difference between \mathcal{S}_2 , \mathcal{S}_3 and \mathcal{S}_4 is the amplitude of the oscillations
 221 in regions III and IV.

222 For the non-oscillatory and flat structures there is excellent agreement between all
 223 higher-order numerical methods at our highest resolution $\Delta x = 10/2^{11}m$. An illustra-
 224 tion of this agreement is given in Figure 3 for \mathcal{S}_2 which is the most difficult to resolve of
 225 the two structures. However, the first-order method \mathcal{V}_1 suppresses oscillations present
 226 in the numerical solutions of other methods due to its diffusive errors [4]. To resolve
 227 these oscillations with \mathcal{V}_1 much lower values of Δx are required.

228 5.1.1. Non-oscillatory Structure

229 The \mathcal{S}_1 “non-oscillatory” structure is the result of a large α , which causes the front
 230 of this flow to not be steep enough to generate undulations over short time periods.
 231 As the system evolves the front will steepen due to non-linearity and undulations will
 232 develop.

233 The structure \mathcal{S}_1 is not present in the literature as no authors chose large enough α
 234 because, such a large α poorly approximates the dam-break problem. An example of
 235 this structure can be seen in Figure 4 for $\alpha = 40m$ using \mathcal{V}_3 with various Δx values.
 236 Because this is not a very steep problem all numerical results are visually identical for
 237 all $\Delta x < 10/2^4m$.

238 From Table 1 it can be seen that not only have these solutions converged visually but
 239 the L_1 measures demonstrate that we have reached convergence to round-off error by
 240 $\Delta x = 10/2^8m$ after which the relative difference between numerical solutions plateau.

Figure 2: Numerical results of \mathcal{V}_3 with $\Delta x = 10/2^{11}m$ (—) at $t = 30s$ for various smooth dam-break problems demonstrating the different observed structures particularly around x_{u_2} (···).

Figure 3: Numerical solutions of \mathcal{D} (—), \mathcal{E} (—), \mathcal{V}_3 (—), \mathcal{V}_2 (—) and \mathcal{V}_1 (—) with $\Delta x = 10/2^{11}m$ at $t = 30s$ for the smooth dam-break problem with $\alpha = 2m$. The Whitham modulation result for the leading wave height A^+ (—) and x_{u_2} (···) are presented for comparison.

Figure 4: Numerical solutions of \mathcal{V}_3 at $t = 30s$ for smooth dam-break problem with $\alpha = 40m$ for $\Delta x = 10/2^{10}m$ (—), $10/2^8m$ (—), $10/2^6m$ (—) and $10/2^4m$ (—). The important quantities A^+ (—), h_2 (—) and x_{u_2} (···) are also presented.

Table 1 also demonstrates that the error in conservation of the numerical solutions are at round-off error for h and \mathcal{H} . The conservation of uh is poor because the smoothed dam-break has such a large α that $h(0m) \neq 1.8m$ and $h(1000m) \neq 1m$, causing unequal fluxes in momentum at the boundaries.

As stated above when $\Delta x = 10/2^{11}m$ the numerical solutions from all methods are identical for this smoothed dam-break problem.

The convergence of the numerical solutions as $\Delta x \rightarrow 0$ to a numerical solution with small error in conservation, independent of the method demonstrates that we have accurately solved the smoothed dam-break problem with $\alpha = 40m$. Therefore, the \mathcal{S}_1 structure should be observed in the solutions of the Serre equations for the smoothed dam-break problem for sufficiently large α .

5.1.2. Flat Structure

The most common structure observed in the literature [1, 2, 9] is the “flat structure” \mathcal{S}_2 . It is observed when the initial conditions are steep enough such that the bore that develops has undulations. This structure consists of oscillations in regions III and IV which are separated by a constant height state around x_{u_2} . An example of the \mathcal{S}_2 structure can be seen in the numerical solutions presented in Figure 5 where $\alpha = 2m$.

As Δx decreases the numerical solutions converge so that by $\Delta x = 10/2^8m$ the solutions for higher Δx are visually identical. Table 1 demonstrates that although we have convergence visually, the L_1 measures are still decreasing and are larger than round-off error. Likewise the C_1 measures are still decreasing and have only reached round-off error for h . This indicates that to attain full convergence of the numerical solutions of this smoothed dam-break problem down to round-off error using \mathcal{V}_3 would require an even smaller Δx . The relative difference between numerical solutions is small and the numerical solutions exhibit good conservation. Therefore, our highest resolution numerical solution is a good approximation to any numerical solutions with lower Δx values. Figure 3 demonstrates that at $\Delta x = 10/2^{11}m$ the numerical solutions of all higher order methods are the same.

α	Δx	C_1^h	C_1^{uh}	$C_1^{\mathcal{H}}$	L_1^h	L_1^u

Table 1: All errors in conservation C_1^q for the conserved quantities and relative differences L_1^q of the primitive variables for numerical solutions of \mathcal{V}_3 . L_1^q uses the numerical solution with $\Delta x = 10/2^{11}m$ as the high resolution basis of comparison and \dagger indicates the omission of the interval $[520m, 540m]$ from the comparison.

Figure 5: Numerical solutions of \mathcal{V}_3 at $t = 30s$ for the smooth dam-break problem with $\alpha = 2m$ for $\Delta x = 10/2^{10}m$ (—), $10/2^8m$ (—), $10/2^6m$ (—) and $10/2^4m$ (—). The important quantities A^+ (—), h_2 (—) and x_{u_2} (···) are also presented.

These results demonstrate that our highest resolution numerical solution is an accurate approximate solution of the Serre equations for the smoothed dam-break problem with $\alpha = 2m$. This implies that the S_2 structure should be observed in solutions of the Serre equations for smooth dam-break problems with similar α values.

These numerical solutions compare well with those of Mitsotakis et al. [9] who use the same α but different h_0 and h_1 values and observe the S_2 structure. We found that we observed this structure for all numerical method's numerical solutions to the smoothed dam-break problem with α values as low as $1m$ and $\Delta x = 10/2^{11}m$. The numerical solutions of Mitsotakis et al. [1] use $\alpha = 1m$ but different heights and observe the structure S_2 . Therefore Mitsotakis et al. [1] and Mitsotakis et al. [9] observe the S_2 structure in their numerical results due to their choice of α for the smoothed dam-break problem.

The first-order method \mathcal{V}_1 is diffusive [4] and damps oscillations that are present in the numerical solutions of higher-order methods as in Figure 3. We find that for any smoothed dam-break problem with $\alpha \leq 4m$ and the dam-break problem only the S_2 structure is observed for the numerical solutions of \mathcal{V}_1 at $t = 30s$ with $\Delta x = 10/2^{11}m$. This is evident in Figure 6 with the numerical solutions of \mathcal{V}_1 using our finest grid where $\Delta x = 10/2^{11}m$ on our steepest initial conditions where $\alpha = 0.001m$. Therefore, Le Métayer et al. [2] using the diffusive \mathcal{V}_1 with their chosen Δx and Δt , which are larger than our Δx and Δt could only observe the S_2 structure for the dam-break problem.

5.1.3. Node Structure

The “node” structure, S_3 was observed by El et al. [8]. The S_3 structure has oscillations throughout regions III and IV that decay to a node at x_{u_2} as can be seen in Figure 7 where $\alpha = 0.4m$.

Figure 7 demonstrates that our numerical solutions have not converged, however this is only in the area around x_{u_2} . Due to the large difference in numerical solutions around x_{u_2} the L_1 measure over the area around x_{u_2} would not be insightful. However,

Figure 6: Numerical solution of \mathcal{V}_1 at $t = 30s$ for the smooth dam-break problem with $\alpha = 0.001m$ for $\Delta x = 10/2^{11}m$ (—).

by omitting this region we can gain some knowledge about how well our solutions agree away from x_{u_2} . This was performed for the relevant L_1 measures in Table 1 by omitting the interval $[520m, 540m]$. These modified L_1 measures demonstrate that while our numerical results have visually converged outside this interval, they have not converged down to round-off error.

Table 1 demonstrates that the C_1 measures are still decreasing and have only attained round-off error for h . Therefore, to resolve the desired convergence of the numerical solutions to one with small error in conservation using \mathcal{V}_3 would require even smaller Δx values.

There is good agreement across different numerical methods for $\Delta x = 10/2^{11}m$ as can be seen in Figure 8. In particular all the higher-order methods exhibit the same structure and only disagree in a very small region around x_{u_2} . We observe that the numerical solution of the worst higher-order method \mathcal{E} has not converged well to the numerical solutions of the other higher-order methods.

We have only obtained a good approximation to the desired numerical solution as $\Delta x \rightarrow 0$ away from x_{u_2} . However, our highest resolution numerical solutions from various higher-order methods are very similar. This suggests that again although we do not have full convergence, our highest resolution numerical solution is a good approximation to the desired numerical solution over the whole domain. Therefore, our highest resolution numerical solutions are an accurate representation of the solutions of the Serre equations for this smoothed dam-break problem. Therefore, the \mathcal{S}_3 structure should be observed in the solutions of the Serre equations for the smoothed dam-break problem with $\alpha = 0.4m$.

These numerical solutions support the findings of El et al. [8] who also use some smoothing [7] but do not report what smoothing was performed. Using their method \mathcal{E} and similar Δx to El et al. [8] we observe the \mathcal{S}_4 “growth” structure in the numerical solution for α values smaller than $0.1m$, indicating that the smoothing performed by El et al. [8] limited their observed behaviour to just the \mathcal{S}_3 structure.

Figure 7: Numerical solutions of \mathcal{V}_3 at $t = 30s$ for the smooth dam-break problem with $\alpha = 0.4m$ for $\Delta x = 10/2^{10}m$ (—), $10/2^8m$ (—), $10/2^6m$ (—) and $10/2^4m$ (—). The important quantities A^+ (—), h_2 (—) and x_{u_2} (···) are also presented.

Figure 8: Numerical solutions of \mathcal{D} (—), \mathcal{E} (—), \mathcal{V}_3 (—) and \mathcal{V}_2 (—) at $t = 30s$ with $\Delta x = 10/2^{11}m$ for the smoothed dam-break problem with $\alpha = 0.4m$. The important quantities A^+ (—) and x_{u_2} (···) are also presented.

5.1.4. Growth Structure

The S_4 “growth” structure, which has hitherto not been commonly published in the literature features a growth in the oscillation amplitude around x_{u_2} . This growth is a result of the interaction of the left and right wave trains, which were predicted by the linear theory of Dougalis et al. [17] to be separate.

An example of the growth structure can be seen for \mathcal{V}_3 ’s numerical solutions in Figure 9 to the smoothed dam-break problem with $\alpha = 0.1m$. This structure was observed in the numerical solutions of \mathcal{V}_3 for $\Delta x = 10/2^{11}m$ at $t = 30s$ for α values as low as $0.001m$ and even for the dam-break problem. The growth structure has also been observed using the finite element method of Mitsotakis et al. [18].

Figure 9 shows that this structure can only be observed for $\Delta x = 10/2^{10}m$, with poor convergence of the numerical results around x_{u_2} . Again our L_1 measures in Table 1 omit the interval $[520m, 540m]$ in the numerical solutions. This demonstrates that although we have visual convergence away from x_{u_2} our numerical solutions have not converged to round-off error as $\Delta x \rightarrow 0$. The C_1 measures in Table 1 are still decreasing and have only attained round-off error for h , although for uh and \mathcal{H} the errors in conservation are small. These measures continue the trend in Table 1 where smaller α ’s and thus steeper initial conditions lead to larger L_1 and C_1 measures because steeper problems are more difficult to solve accurately.

Figure 10 demonstrates that our numerical solutions for $\Delta x = 10/2^{11}m$ with the best methods \mathcal{D} , \mathcal{V}_3 and \mathcal{V}_2 disagree for only a few oscillations around x_{u_2} . Since both \mathcal{D} and \mathcal{E} are second-order finite difference methods their errors are dispersive. These dispersive errors cause the numerical solutions to overestimate the oscillation amplitude of the true solution, particularly around x_{u_2} . Because the dispersive errors of \mathcal{E} are larger than \mathcal{D} more oscillations are observed for the numerical solutions produced by \mathcal{E} . The \mathcal{V}_3 method was shown to be diffusive by Zoppou et al. [4] and therefore its numerical solutions underestimate the oscillation amplitude in the true solution. Therefore, the true solution of the Serre equations should be between the dispersive method \mathcal{D} and the diffusive method \mathcal{V}_3 , and thus will possess the S_4 structure.

The numerical solutions of \mathcal{D} and \mathcal{V}_3 acting as upper and lower bounds respectively for the oscillation amplitude as Δx is reduced is demonstrated in Figure 11 using the maximum of h in the interval $[520m, 540m]$. From this figure it is clear that the amplitudes of the numerical solutions of \mathcal{D} converge down to the limit as the resolution is increased while the numerical solution amplitudes of \mathcal{V}_3 converge up to it. This shows that we have effectively bounded the true solution of the Serre equations. Unfortunately, \mathcal{V}_3 could not be run in reasonable computational times with lower Δx , but the numerical solutions of \mathcal{D} show that doing so is unnecessary.

These results indicate that the solutions of the Serre equations to the smoothed dam-break problem with sufficiently small α values should exhibit a growth structure at $t = 30s$, even though we have not precisely resolved all the oscillations in our numerical solutions.

It was found that decreasing α did increase the amplitude of the oscillations around x_{u_2} . For \mathcal{V}_3 with $\Delta x = 10/2^{11}m$ and $\alpha = 0.001m$ the oscillations in h were bounded by the interval $[1.28m, 1.46m]$. Of particular note is that the number of oscillations are the same in Figures 8 and 10 for the best methods even though they have different

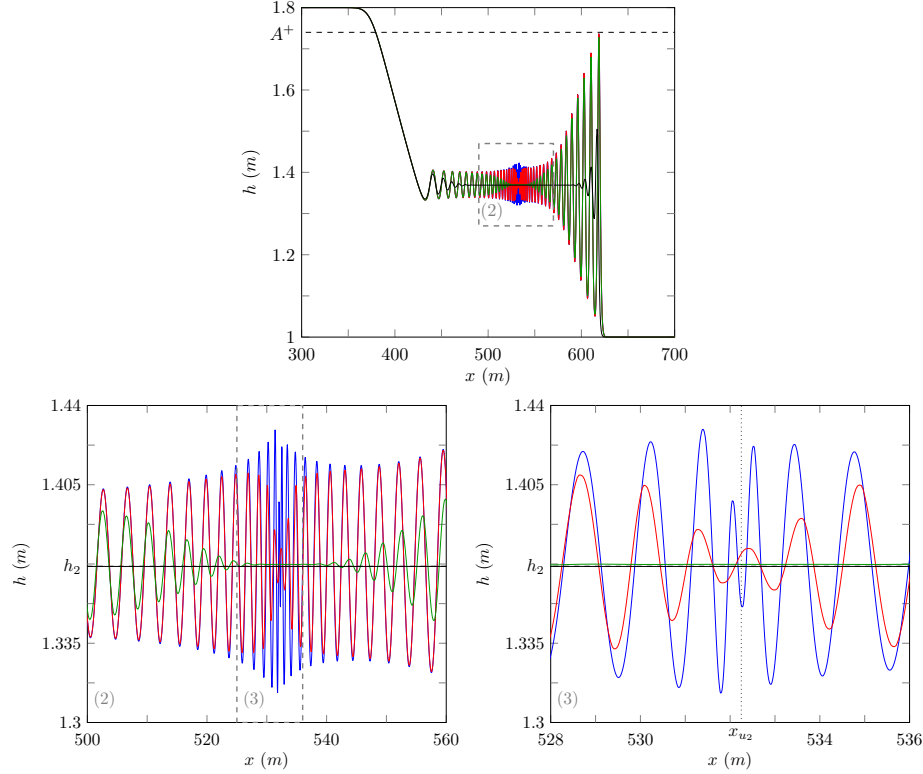

Figure 9: Numerical solutions of \mathcal{V}_3 at $t = 30s$ for the smooth dam-break problem with $\alpha = 0.1m$ for $\Delta x = 10/2^{10}m$ (—), $10/2^8m$ (—), $10/2^6m$ (—) and $10/2^4m$ (—). The important quantities A^+ (—), h_2 (—) and x_{u_2} (···) are also presented.

structures.

By changing the interval and desired time for the numerical solution, Δx could be lowered further so that by $t = 3s$ our numerical solutions have fully converged for α values as low as $0.001m$. This allows us to show that the height of the oscillations around x_{u_2} for the solution of the Serre equation to the smoothed dam-break problem are bounded at $t = 3s$ as $\alpha \rightarrow 0$. Figure 12 demonstrates this for the numerical solutions of \mathcal{V}_3 with $\Delta x = 10/2^{13}m$.

5.2. Shallow water wave equation comparison

The analytical solutions of the shallow water wave equations have been used as a guide for the mean behaviour of the numerical solution of the Serre equations for the dam-break problem in the literature [2, 9].

To assess the applicability of this the mean bore depth and mean fluid velocity in the interval $[x_{u_2} - 50m, x_{u_2} + 50m]$ were calculated from our numerical solution to the smoothed dam-break problem with various height ratios. These means were compared to their approximations from the analytical solution of the dam-break problem for the shallow water wave equations h_2 and u_2 . The results of this can be seen in Figure 13

Figure 10: Numerical solutions of \mathcal{D} (—), \mathcal{E} (—), \mathcal{V}_3 (—) and \mathcal{V}_2 (—) at $t = 30s$ with $\Delta x = 10/2^{11}m$ for the smoothed dam-break problem with $\alpha = 0.1m$. The important quantities A^+ (—) and x_{u_2} (···) are also presented.

Figure 11: Maximum height of numerical solution of the smoothed dam-break problem with $\alpha = 0.4m$ at $t = 30s$ inside the interval $[520m, 540m]$ using \mathcal{D} (□) and \mathcal{V}_3 (○).

Figure 12: Maximum height of numerical solution around x_{u_2} at $t = 3s$ of various smoothed dam-break problem as α decreases, using \mathcal{V}_3 (\square) with $\Delta x = 10/2^{13}m$.

for numerical solutions of \mathcal{V}_3 with $\Delta x = 10/2^9m$ to the smoothed dam-break problem at $t = 100s$ with $\alpha = 0.1m$ where h_0 is fixed and h_1 is varied.

We use a final time of $t = 100s$ as it allows the internal structure of the bore to develop more fully giving a more reliable mean estimate, as a consequence we resort to a coarser grid to keep the run-times reasonable. We find that decreasing Δx does not significantly alter the mean of h and u . We also find that increasing α also does not significantly alter the mean of h and u . Therefore, the mean behaviour of the true solution of the Serre equations to the dam-break problem is captured by these numerical solutions, if it exists.

It can be seen that h_2 and u_2 are good approximations to the mean behaviour of the fluid inside the bore for a range of different aspect ratios. Although, as h_1/h_0 increases this approximation becomes worse, so that h_2 becomes an underestimate and consequently u_2 is an overestimate. Most likely this is due to the increasing influence of non-linearity on the undulations.

We find that for $h_1/h_0 = 1.8$ the mean values of h and u inside the bore for the Serre equations are not equal to h_2 and u_2 . This can be seen in Figure 14 for the numerical solutions of \mathcal{V}_3 with $\Delta x = 10/2^9m$ to the smoothed dam-break problem with $\alpha = 0.1m$ at $t = 300s$. It can be seen that h_2 is an underestimate of h and u_2 is an overestimate of u although the difference between these values and the mean behaviour of the Serre equations is small and only noticeable over long time periods.

The location of the leading wave of the Serre equations slowly diverges from the location of the front of a bore in the shallow water wave equations over long periods of time. This is because the Rankine Hugoniot conditions that determine the front of the bore for the shallow water wave equations are not applicable to dispersive shock waves [7]. This divergence causes the small difference evident in \mathcal{V}_3 's numerical solution to the smoothed dam-break problem with $\alpha = 0.1m$ at $t = 300s$ using $\Delta x = 10/2^9m$, which is shown in Figure 15.

We note that the \mathcal{S}_4 structure present in the numerical solutions using this method and parameters at $t = 30s$ in Figure 9 has decayed away by $t = 300s$ in Figure 14. This is a trend throughout our numerical solutions where oscillation amplitude decreases over time around x_{u_2} , changing the structure of the solution. This can be seen by ob-

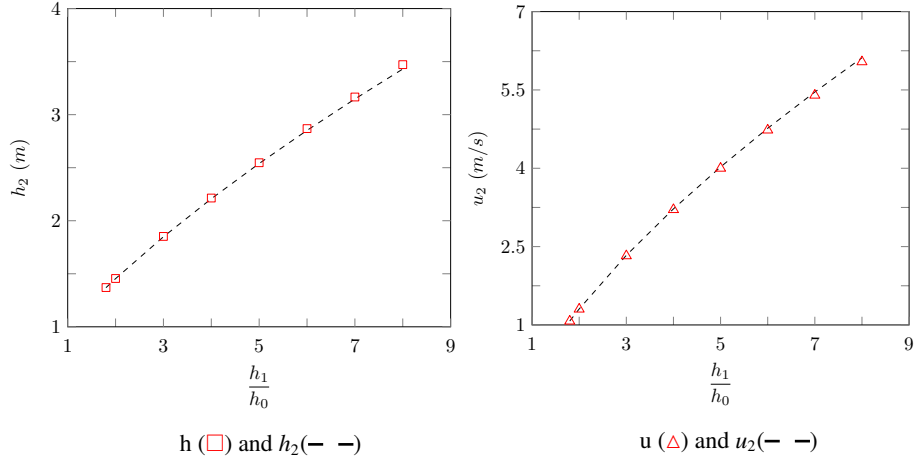

Figure 13: Comparison between mean behaviour inside the bore of the Serre equations and the analytical solution of the shallow water wave equations for a range of different aspect ratios.

Figure 14: The relative difference between h and u and their comparisons h_2 and u_2 plotted around x_{u_2} (\cdots) for \mathcal{V}_3 's solutions with $\Delta x = 10/2^9 m$ for the smoothed dam-break problem with $\alpha = 0.1m$ at $t = 300s$.

417 taining full convergence of the numerical solutions to the smoothed dam-break problem
 418 at $t = 3s$. The converged to numerical solutions for \mathcal{V}_3 are shown in Figure 16. From
 419 this figure it can be seen that the oscillation amplitudes for the numerical solutions for
 420 the smoothed dam-break problems with $\alpha = 0.4m$ and $\alpha = 0.1m$ are much larger at
 421 $t = 3s$ than they are at $t = 30s$ in Figure 2. Since we have demonstrated that our nu-
 422 merical solutions are good approximations to the true solution of the Serre equations at
 423 $t = 30s$ and $t = 3s$, decreasing oscillation amplitude around x_{u_2} over time is probably a
 424 property of the Serre equations. This implies that bounding the oscillation amplitudes
 425 at time $t = 3s$ as was done above, bounds the oscillation amplitudes at all later times.

5.2.1. Contact discontinuity

426 El et al. [8] noted the presence of a ‘degenerate contact discontinuity’ which is
 427 where the two wave trains interact in the \mathcal{S}_3 and \mathcal{S}_4 structures; it travels at the mean
 428 fluid velocity in the bore.
 429

Figure 15: Numerical solution of \mathcal{V}_3 with $\Delta x = 10/2^9 m$ for the smoothed dam-break problem with $\alpha = 0.1m$ at $t = 300s$ around the front of the undular bore. The important quantities A^+ (— —), x_{S_2} (— —) and x_{S+} (— —) are also presented.

Figure 16: Numerical solution of \mathcal{V}_3 with $\Delta x = 10/2^{13} m$ for the smoothed dam-break problem with $\alpha = 0.001m$ (—), $0.1m$ (—) and 0.4 (—) at $t = 3s$. For comparison x_{u_2} (···) is also plotted.

Figure 17: Numerical solution of \mathcal{V}_3 's with $\Delta x = 10/2^9 m$ for the smoothed dam-break problem with $\alpha = 0.1m$ at $t = 30s$ around the contact discontinuity close to x_{u_2} (\cdots).

We observe that as our numerical solutions evolve over time, oscillations appear to be released from the contact discontinuity and travel away from it in both directions, leading to decay of amplitudes around the contact discontinuity. Therefore, the contact discontinuity is an important feature and its behaviour determines the structure of the oscillations in regions III and IV.

The different speeds of the oscillations are determined by the phase velocity, which for the Serre equations linearised around the mean height \bar{h} and mean velocity \bar{u} in regions III and IV of the solution to the dam-break problem is

$$v_p = \bar{u} \pm \sqrt{g\bar{h}} \sqrt{\frac{3}{\bar{h}^2 k^2 + 3}} \quad (6)$$

with wave number k . It can be seen that as $k \rightarrow \infty$ then $v_p \rightarrow \bar{u}$ and as $k \rightarrow 0$ then $v_p \rightarrow \bar{u} \pm \sqrt{g\bar{h}}$. The left wave train corresponds to the $-$ branch of the phase velocity while the right wave train corresponds to the $+$ branch of the phase velocity. The contact discontinuity corresponds to the high wave-number limit of these two wave trains. Because the two wave trains correspond to the $-$ and $+$ branches of the phase velocity for the left wave train h and u are in-phase, while for the right wave train h and u are out-of-phase. This can be seen in Figure 17 for the numerical solutions of \mathcal{V}_3 with $\Delta x = 10/2^9 m$ for the smoothed dam-break problem with $\alpha = 0.1m$ at $t = 30s$.

The $+$ branch of the phase velocity is strictly increasing in k , while the $-$ branch is strictly decreasing. It can also be shown that $+$ branch and $-$ negative branch of the group velocity behave in the same way with the same limits as their phase velocity counterparts. Therefore as in Dougalis et al. [17] the linear theory predicts separate dispersive wave trains. However, we have demonstrated that in the short term these wave trains should not be separate and so the interaction of these wave trains in the \mathcal{S}_3 and \mathcal{S}_4 is caused by non-linear effects.

5.3. Whitham Modulation Comparison

El et al. [8] demonstrated that their Whitham modulation results approximated the numerical solutions of the smoothed dam-break problem well for a range of aspect ra-

Figure 18: Relative difference between Whitham modulation result A^+ and the leading wave amplitude A from our numerical solutions of \mathcal{V}_3 with $\Delta x = 10/2^9 m$ for the smoothed dam-break problem with $\alpha = 0.1m$ over time.

458 tions. We observed that the Whitham modulation results are an underestimate compared to
459 our numerical solutions.

460 This can be seen in Figure 18 as the relative difference between A^+ from El et al. [8]
461 and the leading wave amplitude of our numerical solution A does not converge to 0 over
462 time. Since we find that the numerical solutions for the smoothed dam-break problem
463 with $\alpha = 0.1m$ have converged for the front of the undular bore by $\Delta x = 10/2^8 m$ as
464 in Figure 9, our numerical solutions for A are considered reliable. We also note that
465 unlike the oscillations around x_{u_2} the leading wave amplitude increases over time.

466 The Whitham modulation results for the location of the leading wave x_{S^+} is a better
467 approximation than that given by the shallow water wave equations x_{S_2} , as can be seen
468 in Figure 15. This is due to the inapplicability of the Rankine Hugoniot conditions
469 from which S_2 is derived for dispersive shock waves [7].

470 The agreement between the Whitham modulation results and our numerical solu-
471 tions is actually quite good given that the Whitham modulations results are an asymp-
472 totic solution to the dam-break problem. We include them here as a counter point to the
473 results of El et al. [8] and Mitsotakis et al. [9], as from their results one would expect
474 that numerical solutions should only ever underestimate A^+ and S^+ when the ratio of
475 the water depth in the bore to still water in front of it Δ is less than the critical value
476 1.43.

477 6. Conclusions

478 Utilising two finite difference methods of second-order and three finite difference
479 finite volume methods of various orders to solve the nonlinear weakly dispersive Serre
480 equations an investigation into the smoothed dam-break problem with varying steep-
481 ness was performed. Four different structures of the numerical solutions were observed
482 and demonstrated to be valid, the general trend of these structures is that an increase
483 in steepness increases the size and number of oscillations in the solution. This study
484 explains the different structures exhibited by the numerical results in the literature for
485 the smoothed dam-break problem for the Serre equations and uncovers a new result.
486 These results demonstrate that other methods in the literature could replicate our results

if their simulations are extended. Furthermore, these results suggest that this new result and its associated structure is to be expected for the solution of the Serre equation to the dam-break problem at least for short enough time spans, if it exists.

We confirm that the analytical solution of the shallow water wave equations for the dam-break problem provides a reasonable approximation to the mean height and velocity inside the bore formed by the smoothed dam-break problem for the Serre equations across a range of aspect ratios. Finally, we observe that the Whitham modulations results for the leading wave of an undular bore can underestimate the leading wave amplitude and speed when the bore height is below the critical value.

542 Appendix A.

543 The methods \mathcal{E} and \mathcal{D} use the centred second-order finite difference approximation
 544 to the momentum equation (1b), denoted as \mathcal{D}_u . For the mass equation (1a) \mathcal{E} uses the
 545 two step Lax-Wendroff method, denoted as \mathcal{E}_h while \mathcal{D} uses a centred second-order
 546 finite difference approximation, denoted as \mathcal{D}_h .

547 Appendix A.1. \mathcal{D}_u for the Momentum Equation

548 First (1b) is expanded to get

$$549 \quad h \frac{\partial u}{\partial t} - h^2 \frac{\partial^2 u}{\partial x \partial t} - \frac{h^3}{3} \frac{\partial^3 u}{\partial x^2 \partial t} = -X$$

551 where X contains only spatial derivatives and is

$$552 \quad X = uh \frac{\partial u}{\partial x} + gh \frac{\partial h}{\partial x} + h^2 \frac{\partial u}{\partial x} \frac{\partial u}{\partial x} + \frac{h^3}{3} \frac{\partial u}{\partial x} \frac{\partial^2 u}{\partial x^2} - h^2 u \frac{\partial^2 u}{\partial x^2} - \frac{h^3}{3} u \frac{\partial^3 u}{\partial x^3}.$$

554 All derivatives are approximated by second-order centred finite difference approxi-
 555 mations on a uniform grid in space and time, which after rearranging into an update
 556 formula becomes

$$557 \quad h_i^n u_i^{n+1} - (h_i^n)^2 \left(\frac{u_{i+1}^{n+1} - u_{i-1}^{n+1}}{2\Delta x} \right) - \frac{(h_i^n)^3}{3} \left(\frac{u_{i+1}^{n+1} - 2u_i^{n+1} + u_{i-1}^{n+1}}{\Delta x^2} \right) = -Y_i^n \quad (\text{A.1})$$

559 where

$$560 \quad Y_i^n = 2\Delta t X_i^n - h_i^n u_i^{n-1} + (h_i^n)^2 \left(\frac{u_{i+1}^{n-1} - u_{i-1}^{n-1}}{2\Delta x} \right) + \frac{(h_i^n)^3}{3} \left(\frac{u_{i+1}^{n-1} - 2u_i^{n-1} + u_{i-1}^{n-1}}{\Delta x^2} \right)$$

562 and

$$563 \quad X_i^n = u_i^n h_i^n \frac{u_{i+1}^n - u_{i-1}^n}{2\Delta x} + gh_i^n \frac{h_{i+1}^n - h_{i-1}^n}{2\Delta x} + (h_i^n)^2 \left(\frac{u_{i+1}^n - u_{i-1}^n}{2\Delta x} \right)^2$$

$$564 \quad + \frac{(h_i^n)^3}{3} \frac{u_{i+1}^n - u_{i-1}^n}{2\Delta x} \frac{u_{i+1}^n - 2u_i^n + u_{i-1}^n}{\Delta x^2} - (h_i^n)^2 u_i^n \frac{u_{i+1}^n - 2u_i^n + u_{i-1}^n}{\Delta x^2}$$

$$565 \quad - \frac{(h_i^n)^3}{3} u_i^n \frac{u_{i+2}^n - 2u_{i+1}^n + 2u_{i-1}^n - u_{i-2}^n}{2\Delta x^3}.$$

568 Equation (A.1) can be rearranged into an explicit update scheme \mathcal{D}_u for u given its
 569 current and previous values, so that

$$570 \quad \begin{bmatrix} u_0^{n+1} \\ \vdots \\ u_m^{n+1} \end{bmatrix} = A^{-1} \begin{bmatrix} -Y_0^n \\ \vdots \\ -Y_m^n \end{bmatrix} =: \mathcal{D}_u(\mathbf{u}^n, \mathbf{h}^n, \mathbf{u}^{n-1}, \Delta x, \Delta t) \quad (\text{A.2})$$

572 where A is a tri-diagonal matrix.

573 *Appendix A.2. Numerical Methods for the Mass Equation*

574 The two step Lax-Wendroff update \mathcal{E}_h for h is

$$575 \quad h_{i+1/2}^{n+1/2} = \frac{1}{2} (h_{i+1}^n + h_i^n) - \frac{\Delta t}{2\Delta x} (u_{i+1}^n h_{i+1}^n - h_i^n u_i^n),$$

576

577

$$578 \quad h_{i-1/2}^{n+1/2} = \frac{1}{2} (h_i^n + h_{i-1}^n) - \frac{\Delta t}{2\Delta x} (u_i^n h_i^n - h_{i-1}^n u_{i-1}^n)$$

579

580 and

$$581 \quad h_i^{n+1} = h_i^n - \frac{\Delta t}{\Delta x} (u_{i+1/2}^{n+1/2} h_{i+1/2}^{n+1/2} - u_{i-1/2}^{n+1/2} h_{i-1/2}^{n+1/2}).$$

582

583 The quantities $u_{i\pm 1/2}^{n+1/2}$ are calculated using u^{n+1} obtained by applying \mathcal{D}_u (A.2) to u^n
 584 then linearly interpolating in space and time to give

$$585 \quad u_{i+1/2}^{n+1/2} = \frac{u_{i+1}^{n+1} + u_{i+1}^n + u_i^{n+1} + u_i^n}{4}$$

586

587 and

$$588 \quad u_{i-1/2}^{n+1/2} = \frac{u_i^{n+1} + u_i^n + u_{i-1}^{n+1} + u_{i-1}^n}{4}.$$

589

590 Thus we have the following update scheme \mathcal{E}_h for (1a)

$$591 \quad \mathbf{h}^{n+1} = \mathcal{E}_h(\mathbf{u}^n, \mathbf{h}^n, \mathbf{u}^{n+1}, \Delta x, \Delta t). \quad (\text{A.3})$$

592

593 The second order centered finite difference approximation to the conservation of
 594 mass equation (1a) is

$$595 \quad h_i^{n+1} = h_i^{n-1} - \Delta t \left(u_i^n \frac{h_{i+1}^n - h_{i-1}^n}{\Delta x} + h_i^n \frac{u_{i+1}^n - u_{i-1}^n}{\Delta x} \right).$$

596

597 Thus we have an update scheme \mathcal{D}_h for all i

$$598 \quad \mathbf{h}^{n+1} = \mathcal{D}_h(\mathbf{u}^n, \mathbf{h}^n, \mathbf{h}^{n-1}, \Delta x, \Delta t). \quad (\text{A.4})$$

599

600 *Appendix A.3. Complete Method*

601 The method \mathcal{E} is the combination of (A.3) for (1a) and (A.2) for (1b) in the follow-
 602 ing way

$$603 \quad \left. \begin{aligned} \mathbf{u}^{n+1} &= \mathcal{D}_u(\mathbf{u}^n, \mathbf{h}^n, \mathbf{u}^{n-1}, \Delta x, \Delta t) \\ \mathbf{h}^{n+1} &= \mathcal{E}_h(\mathbf{u}^n, \mathbf{h}^n, \mathbf{u}^{n+1}, \Delta x, \Delta t) \end{aligned} \right\} \mathcal{E}(\mathbf{u}^n, \mathbf{h}^n, \mathbf{u}^{n-1}, \mathbf{h}^{n-1}, \Delta x, \Delta t). \quad (\text{A.5})$$

604

605 The method \mathcal{D} is the combination of (A.4) for (1a) and (A.2) for (1b) in the follow-
 606 ing way

$$607 \quad \left. \begin{aligned} \mathbf{h}^{n+1} &= \mathcal{D}_h(\mathbf{u}^n, \mathbf{h}^n, \mathbf{h}^{n-1}, \Delta x, \Delta t) \\ \mathbf{u}^{n+1} &= \mathcal{D}_u(\mathbf{u}^n, \mathbf{h}^n, \mathbf{u}^{n-1}, \Delta x, \Delta t) \end{aligned} \right\} \mathcal{D}(\mathbf{u}^n, \mathbf{h}^n, \mathbf{u}^{n-1}, \mathbf{h}^{n-1}, \Delta x, \Delta t). \quad (\text{A.6})$$

608
