## Abstract

We use numerical methods to study the short term behaviour of the Serre equations in the presence of steep gradients because there are no known analytical solutions for these problems. In keeping with the literature we study a class of initial condition problems that are a smooth approximation to the initial conditions of the dam-break problem. This class of initial condition problems allow us to observe the behaviour of the Serre equations with varying steepness of the initial conditions. The numerical solutions of the Serre equations are justified by demonstrating that as the resolution increases they converge to a solution with little error in conservation of mass, momentum and energy independent of the numerical method. We observe and justify four different structures of the converged numerical solutions depending on the steepness of the initial conditions. Two of these structures were observed in the literature, with the other two not being commonly found in the literature. The numerical solutions are then used to assess how well the analytical solution of the shallow water wave equations captures the mean behaviour of the solution of the Serre equations for the dam-break problem in the short term. Lastly the numerical solutions are compared to asymptotic results in the literature to approximate the depth and location of the front of an undular bore.

*Keywords:* Serre equations, steep gradients, dam break

---

## 1. Introduction

The behaviour of flows containing steep gradients are important to a range of problems in shallow water such as the propagation of a bore, the dam-break problem and shoaling waves on a beach.

The Serre equations are used as a compromise between the non-dispersive shallow water wave equations and the incompressible inviscid Euler equations for modelling dispersive waves of the free surface in the presence of steep gradients, which are present for the Euler equations [1] but not for the shallow water wave equations. The

9 Serre equations like the shallow water wave equations produce methods [2–4] that are  
10 computationally easier and quicker to solve than the best methods for the Euler equa-  
11 tions. The Serre equations are considered the most appropriate approximation to the  
12 Euler equations for modelling dispersive waves up to the shore line [5, 6]. Therefore,  
13 understanding the behaviour of the Serre equations in the presence of steep gradients  
14 offers some insight into the behaviour of steep gradients for fluids more generally.

15 There are no known analytical solutions to problems containing steep gradients for  
16 the Serre equations. To infer the structure of solutions to problems containing steep  
17 gradients in the near term we have to resort to investigating numerical solutions of the  
18 Serre equations for these problems. Whereas utilising modulation theory the long term  
19 behaviour of steep gradient flows for dispersive equations can be understood; with El  
20 and Hoefer [7] providing a review of these results for dispersive shock waves.

21 There are few examples in the literature which depict the short term behaviour of  
22 numerical solutions to the Serre equations in the presence of steep gradients [1–4, 8,  
23 9]. These papers all present problems with discontinuous initial conditions [2–4] or a  
24 smooth approximation to them when the numerical method requires some smoothness  
25 of the solutions [1, 8, 9]. Among these papers there are differences in the structures  
26 of the numerical solutions, with some demonstrating undulations in depth and velocity  
27 throughout the bore [3, 4, 8] and others showing a constant depth and velocity state in  
28 the middle of the bore [1, 2, 9].

29 The short term mean behaviour of numerical solutions to the dam-break problem  
30 for the Serre equations is consistent across the literature [1–4, 8, 9]. In the long term  
31 the mean behaviour of the solution of the Serre equations to the dam-break problem is  
32 given by the analytical solution of the shallow water wave equations to the dam-break  
33 problem [7].

34 Utilising modulation theory expressions for the long term leading wave amplitude  
35 and speed of an undular bore for the Serre equations were derived and verified for a  
36 range of undular bores by El et al. [8]. These expressions were also shown to be valid  
37 for all the different structures found in the literature [8, 9].

38 The first aim of this paper is to investigate and explain why different short term be-  
39 haviour has been published in the literature for numerical solutions of the Serre equa-  
40 tions for problems containing steep gradients. We find that the undulations of a bore  
41 can be damped to a constant depth and velocity state by the numerical diffusion in-  
42 troduced by the method, as is the case for Le Métayer et al. [2]. Oscillation damping  
43 can also occur due to the particular smoothing of the initial conditions, as is the case  
44 for Mitsotakis et al. [1], El et al. [8] and Mitsotakis et al. [9]. Our results demonstrate  
45 that in the short term our ‘growth’ structure is the structure that should be observed for  
46 the solution of the dam-break problem for the Serre equations. While over long time  
47 periods the Serre equations damps this ‘growth’ structure, which is consistent with  
48 the expected long term behaviour. However, this natural decay is dominated by other  
49 factors in the literature for numerical solutions over short time spans.

50 The second aim of this paper is to compare our numerical solutions with the an-  
51 alytical solution of the shallow water wave equations and the Whitham modulation  
52 results of El et al. [8]. We confirm that for a range of dam-break problems the analyti-  
53 cal solution of the shallow water wave equations captures the mean depth and velocity  
54 of the numerical solution of the Serre equations, as in the literature [2, 7, 9]. It was

55 also found that the results of El et al. [8] are a good approximation to our numeri-  
 56 cal solutions. However, unlike the results of El et al. [8] and Mitsotakis et al. [9] we  
 57 demonstrate that the Whitham modulation results can underestimate the leading wave  
 58 height and speed in the near term, even when the ratio of the two water depths is below  
 59 the critical value.

60 The first aim of this paper is achieved by demonstrating that our numerical solutions  
 61 are good approximations to the true solutions of the Serre equations. This is accom-  
 62 plished by demonstrating that as the resolution of a particular method is increased, the  
 63 numerical solutions converge to a numerical solution with little error in the conserva-  
 64 tion of mass, momentum and energy. The numerical solution is also consistent across  
 65 the five different numerical methods. Three of the methods are the first, second and  
 66 third-order methods presented by Zoppou et al. [4]. The first-order method is equiva-  
 67 lent to the method of Le Métayer et al. [2]. The fourth method is a recreation of the  
 68 second-order method used by El et al. [8]. Lastly, the fifth method is a second-order  
 69 finite difference approximation to the Serre equations.

70 The second aim is accomplished by comparing our verified numerical solutions to  
 71 the analytical solutions of the shallow water wave equations and the Whitham modula-  
 72 tion results presented by El et al. [8].

73 The paper is organised as follows, in Section 2 the Serre equations and the quan-  
 74 tities they conserve are presented. In Section 3 the smoothed dam-break problem is  
 75 defined and the notation for the measures of the relative difference between numerical  
 76 solutions and the relative error in the conserved quantities is introduced. An analytical  
 77 solution of the shallow water wave equations and the notation for the amplitude and  
 78 speed of the leading wave of an undular bore are presented. In Section 4 the numerical  
 79 methods and their important properties are presented. In Section 5 the four different  
 80 structures in the solutions of smoothed dam-break problem for the Serre equations are  
 81 determined using verified numerical solutions. The verified numerical solutions are  
 82 also used to compare the analytical solution of the shallow water wave equations to the  
 83 mean behaviour of the solution of the Serre equations for the dam-break problem. The  
 84 Whitham modulations results are also compared to the verified numerical solutions.

## 85 2. Serre Equations

86 The Serre equations can be derived by integrating the full inviscid incompressible  
 87 Euler equations over the water depth [10]. They can also be derived as an asymptotic  
 88 expansion of the Euler equations [11]. Assuming a constant horizontal bed, the one-  
 89 dimensional Serre equations are [12]

$$90 \quad \frac{\partial h}{\partial t} + \frac{\partial(uh)}{\partial x} = 0 \quad (1a)$$

92 and

$$93 \quad \underbrace{\frac{\partial(uh)}{\partial t} + \frac{\partial}{\partial x} \left( u^2 h + \frac{gh^2}{2} \right)}_{\text{Shallow Water Wave Equations}} + \underbrace{\frac{\partial}{\partial x} \left( \frac{h^3}{3} \left[ \frac{\partial u}{\partial x} \frac{\partial u}{\partial x} - u \frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial x \partial t} \right] \right)}_{\text{Dispersion Terms}} = 0. \quad (1b)$$

94 Serre Equations

95 Where  $u(x, t)$  is the horizontal velocity over the depth of water  $h(x, t)$ ,  $g$  is the acceler-  
 96 ation due to gravity,  $x$  is the horizontal spatial variable and  $t$  is time.

97 The Serre equations are conservation laws for ‘mass’ (1a), ‘momentum’ (1b) and  
 98 the Hamiltonian [13, 14]

$$99 \quad \mathcal{H}(x, t) = \frac{1}{2} \left( hu^2 + \frac{h^3}{3} \left( \frac{\partial u}{\partial x} \right)^2 + gh^2 \right) \quad (2)$$

100  
 101 which is the total energy.

### 102 3. Smoothed Dam Break Problem

103 In this section we define a class of initial condition problems, called the smoothed  
 104 dam-break problem that we use throughout our numerical investigation. This class of  
 105 initial conditions are used in the literature [1, 9] to smoothly approximate the discontin-  
 106 uous initial conditions of the dam-break problem, as some numerical methods require  
 107 smoothness of the solutions.

108 The smoothed dam-break problem has the following initial conditions

$$109 \quad h(x, 0) = h_0 + \frac{h_1 - h_0}{2} \left( 1 + \tanh \left( \frac{x_0 - x}{\alpha} \right) \right) m, \quad (3a)$$

110  
 111 and

$$112 \quad u(x, 0) = 0.0 \text{ m/s}. \quad (3b)$$

113  
 114 This represents a smooth transition centred around  $x_0$  between a water depth of  $h_0$   
 115 on the right which is smaller than the water depth of  $h_1$  on the left. Here  $\alpha$  measures  
 116 the distance over which approximately 46% of that smooth transition between the two  
 117 heights occurs. These are the same  $h_0$  and  $h_1$  values as those of the smoothed dam-  
 118 break problem of El et al. [8] and the dam-break problem of Le Métayer et al. [2].

119 There are no known analytical solutions of the Serre equations for the dam-break  
 120 problem or an arbitrary smoothed dam-break problem. Therefore, to demonstrate that  
 121 our numerical solutions converge we use the relative difference between numerical  
 122 solutions  $L_1^h$  and  $L_1^u$  for the primitive variables  $h$  and  $u$  respectively. To demonstrate that  
 123 our numerical solutions conserve the quantities  $h$ ,  $uh$  and  $\mathcal{H}$  well we use the relative  
 124 error of their conservation  $C_1^h$ ,  $C_1^{uh}$  and  $C_1^{\mathcal{H}}$  respectively.

#### 125 3.1. Background for derived and observed comparisons

126 Because there are no known analytic solutions to the dam-break problem for the  
 127 Serre equations the literature has relied on comparisons to simpler equations such as  
 128 the shallow water wave equations [2, 9] or asymptotic solutions [7, 8] to understand  
 129 the behaviour of the Serre equations for the dam-break problem.

130 For instance the analytical solution of the shallow water wave equations for the  
 131 dam-break problem captures the mean behaviour of the solutions of the Serre equations  
 132 to the dam-break problem in the long term [7]. This was also demonstrated for the

Figure 1: Analytical solution at  $t = 30s$  of the dam-break problem for the shallow water wave equations with  $h_0 = 1m$ ,  $h_1 = 1.8m$  and  $x_0 = 500m$ .

short term numerical solutions of the Serre equations for a dam-break problem [2] and a smoothed dam-break problem [9].

An example of the analytical solution of the shallow water wave equations for the dam-break problem is presented in Figure 1. Region I is the undisturbed water upstream of the dam-break at constant height ( $h_1$ ) and velocity ( $0m/s$ ). Region II is the rarefaction fan connecting regions I and III. Regions III and IV compose the constant height ( $h_2$ ) and constant velocity ( $u_2$ ) state, with the regions separated by  $x_{u_2} = x_0 + u_2 t$ . Region V is the undisturbed water downstream at constant height ( $h_0$ ) and velocity ( $0m/s$ ) separated from Region IV by a shock which travels at velocity  $S_2$ . Expressions for the unknown quantities  $h_2$ ,  $u_2$  and  $S_2$  in terms of  $h_0$  and  $h_1$  are known, with the expressions of Wu et al. [15] requiring the solution of a single non-linear equation.

For our dam-break heights of interest;  $h_0 = 1m$  and  $h_1 = 1.8m$  we have  $h_2 = 1.36898m$ ,  $u_2 = 1.074975 m/s$ ,  $S_2 = 3.98835 m/s$  and  $x_{u_2} = 532.24925m$  which are shown in Figure 1 for  $t = 30s$ . The location of the front of the bore for the shallow water wave equations at time  $t$  is thus  $x_{S_2} = x_0 + S_2 t$  so that  $x_{S_2} = 619.6505m$  at  $t = 30s$ .

Utilizing Whitham modulation theory for a one-phase periodic travelling wave asymptotic expressions for the amplitude  $A^+$  and speed  $S^+$  of the leading wave were derived by El et al. [8]. These expressions were found to be most appropriate for dam-break aspect ratios  $h_1/h_0 \leq 1.94$ .

For our dam-break heights of interest  $h_0 = 1m$  and  $h_1 = 1.8m$  we obtain  $A^+ = 1.73998m$  and  $S^+ = 4.13148m/s$ . The location of the leading wave of an undular bore at time  $t$  is then  $x_{S^+} = x_0 + S^+ t$  so that  $x_{S^+} = 623.9444m$  for  $t = 30s$ .

#### 4. Numerical Methods

Five numerical schemes were used to investigate the behaviour of the Serre equations in the presence of steep gradients, the first ( $\mathcal{V}_1$ ), second ( $\mathcal{V}_2$ ) and third-order ( $\mathcal{V}_3$ ) finite difference finite volume methods of Zoppou et al. [4], the second-order finite difference method of El et al. [8] ( $\mathcal{E}$ ) and a second-order finite difference method ( $\mathcal{D}$ ) that can be found in the Appendix.

The  $\mathcal{V}_i$  methods are stable under a Courant-Friederichs-Lewy (CFL) condition presented by A. Harten [16]. The  $\mathcal{V}_i$  methods have demonstrated the appropriate order of convergence for smooth problems [4]. Furthermore,  $\mathcal{V}_2$  and  $\mathcal{V}_3$  have been validated against experimental data containing steep gradients [4]. The two methods  $\mathcal{D}$  and  $\mathcal{E}$  were found to be stable under the same CFL condition.

Generally, we found that  $\mathcal{V}_1$  is the worst performing method due to its numerical diffusion [4]. Of the high-order methods  $\mathcal{E}$  is the worst performing, introducing dispersive errors.

## 5. Numerical Results

We investigate the behaviour of the Serre equations in the presence of steep gradients by numerically solving the smoothed dam-break problem while varying the steepness of the initial conditions. As  $\Delta x \rightarrow 0$  our numerical solutions should represent a good approximation of the true solution of the Serre equations. If our numerical solutions to a smoothed dam-break problem converge to the same numerical solution with little error in conservation of mass, momentum and energy as  $\Delta x \rightarrow 0$  for each method, then this numerical solution is considered an accurate approximate solution to that smoothed dam-break problem for the Serre equations.

This process validates our numerical solutions for the smoothed dam-break problem, and thus validates our numerical methods to approximate the solution of the Serre equations in the presence of steep gradients, if it exists. With a validated model we can compare the numerical solution to the analytical solution of the shallow water wave equations for the dam-break problem and the results of El et al. [8].

Throughout most of this section we are interested in the numerical solution at  $t = 30s$  to the smoothed dam-break problem with  $h_0 = 1m$ ,  $h_1 = 1.8m$  and  $x_0 = 500m$  while allowing for different  $\alpha$  values. All numerical methods used  $\Delta t = 0.01\Delta x$  which is smaller than required by the CFL condition, ensuring stability of our schemes. The method  $\mathcal{V}_2$  requires an input parameter to its slope limiter and this was chosen to be  $\theta = 1.2$  [4]. The spatial domain was  $[0m, 1000m]$  with the following Dirichlet boundary conditions,  $u = 0m/s$  at both boundaries,  $h = 1.8m$  on the left and  $h = 1m$  on the right.

### 5.1. Observed Structures of the Numerical Solutions

We observe that there are four different structures for the converged to numerical solution depending on the chosen  $\alpha$ . They are the ‘non-oscillatory’ structure  $\mathcal{S}_1$ , the ‘flat’ structure  $\mathcal{S}_2$ , the ‘node’ structure  $\mathcal{S}_3$  and the ‘growth’ structure  $\mathcal{S}_4$ . An example of each of these structures is shown in Figure 2 which were obtained using  $\mathcal{V}_3$  with  $\Delta x = 10/2^{11}m$ .

The four structures are identified by the dominant features of the numerical solutions in regions III and IV. They also correspond to different structures in the numerical solutions that have been presented in the literature. From Figure 2 it can be seen that as  $\alpha$  is decreased, steepening the initial conditions, the numerical solutions demonstrate an increase in the size and number of oscillations particularly around  $x_{u_2} = x_0 + u_2t$ . We observe that the difference between  $\mathcal{S}_2$ ,  $\mathcal{S}_3$  and  $\mathcal{S}_4$  is the amplitude of the oscillations in regions III and IV.

Figure 2: Numerical results of  $\mathcal{V}_3$  with  $\Delta x = 10/2^{11}m$  (—) at  $t = 30s$  for various smooth dam-break problems demonstrating the different observed structures particularly around  $x_{u_2}$  ( $\cdots$ ).

Figure 3: Numerical solutions of  $\mathcal{D}$  (—),  $\mathcal{E}$  (—),  $\mathcal{V}_3$  (—),  $\mathcal{V}_2$  (—) and  $\mathcal{V}_1$  (—) with  $\Delta x = 10/2^{11}m$  at  $t = 30s$  for the smooth dam-break problem with  $\alpha = 2m$ . The Whitham modulation result for the leading wave height  $A^+$  (—) and  $x_{u_2}$  (···) are presented for comparison.

For the non-oscillatory and flat structures there is excellent agreement between all higher-order numerical methods at our highest resolution  $\Delta x = 10/2^{11}m$ . An illustration of this agreement is given in Figure 3 for  $\mathcal{S}_2$  which is the most difficult to resolve of the two structures. However, the first-order method  $\mathcal{V}_1$  suppresses oscillations present in the numerical solutions of other methods due to its diffusive errors [4]. To resolve these oscillations with  $\mathcal{V}_1$  lower values of  $\Delta x$  are required.

#### 5.1.1. Non-oscillatory Structure

The  $\mathcal{S}_1$  “non-oscillatory” structure is the result of a large  $\alpha$ , which causes the front of this flow to not be steep enough to generate undulations over short time periods. As the system evolves the front will steepen due to non-linearity and undulations will develop.

The structure  $\mathcal{S}_1$  is not present in the literature as no authors chose large enough  $\alpha$  because, such a large  $\alpha$  poorly approximates the dam-break problem. An example of this structure can be seen in Figure 4 for  $\alpha = 40m$  using  $\mathcal{V}_3$  with various  $\Delta x$  values. Because this is not a very steep problem all numerical results are visually identical for all  $\Delta x < 10/2^4m$ .

From Table 1 it can be seen that not only have these solutions converged visually but the  $L_1$  measures demonstrate that we have reached convergence to round-off error by  $\Delta x = 10/2^8m$  after which the relative difference between numerical solutions plateau.

Table 1 also demonstrates that the error in conservation of the numerical solutions are at round-off error for  $h$  and  $\mathcal{H}$ . The conservation of  $uh$  is poor because the smoothed dam-break has such a large  $\alpha$  that  $h(0m) \neq 1.8m$  and  $h(1000m) \neq 1m$ , causing unequal fluxes in momentum at the boundaries.

As stated above when  $\Delta x = 10/2^{11}m$  the numerical solutions from all methods are identical for this smoothed dam-break problem.

The convergence of the numerical solutions as  $\Delta x \rightarrow 0$  to a numerical solution with small error in conservation, independent of the method demonstrates that we have accurately solved the smoothed dam-break problem with  $\alpha = 40m$ . Therefore, the  $\mathcal{S}_1$

Figure 4: Numerical solutions of  $\mathcal{V}_3$  at  $t = 30s$  for smooth dam-break problem with  $\alpha = 40m$  for  $\Delta x = 10/2^{10}m$  (—),  $10/2^8m$  (—),  $10/2^6m$  (—) and  $10/2^4m$  (—). The important quantities  $A^+$  (—),  $h_2$  (—) and  $x_{u_2}$  (···) are also presented.

structure should be observed in the solutions of the Serre equations for the smoothed dam-break problem for sufficiently large  $\alpha$ .

#### 5.1.2. Flat Structure

The most common structure observed in the literature [1, 2, 9] is the “flat structure”  $\mathcal{S}_2$ . It is observed when the initial conditions are steep enough such that the bore that develops has undulations. This structure consists of oscillations in regions III and IV which are separated by a constant height state around  $x_{u_2}$ . An example of the  $\mathcal{S}_2$  structure can be seen in the numerical solutions presented in Figure 5 where  $\alpha = 2m$ .

As  $\Delta x$  decreases the numerical solutions converge so that by  $\Delta x = 10/2^8m$  the solutions for lower  $\Delta x$  are visually identical. Table 1 demonstrates that although we have convergence visually, the  $L_1$  measures are still decreasing and are larger than round-off error. Likewise the  $C_1$  measures are still decreasing and have only reached round-off error for  $h$ . This indicates that to attain full convergence of the numerical solutions of this smoothed dam-break problem down to round-off error using  $\mathcal{V}_3$  would require an even smaller  $\Delta x$ . The relative difference between numerical solutions is small and the numerical solutions exhibit good conservation. Therefore, our highest resolution numerical solution is a good approximation to any numerical solutions with lower  $\Delta x$  values. Figure 3 demonstrates that at  $\Delta x = 10/2^{11}m$  the numerical solutions of all higher order methods are the same.

These results demonstrate that our highest resolution numerical solution is an accurate approximate solution of the Serre equations for the smoothed dam-break problem with  $\alpha = 2m$ . This implies that the  $\mathcal{S}_2$  structure should be observed in solutions of the Serre equations for smooth dam-break problems with similar  $\alpha$  values.

These numerical solutions compare well with those of Mitsotakis et al. [9] who use the same  $\alpha$  but different  $h_0$  and  $h_1$  values and observe the  $\mathcal{S}_2$  structure. We found that we observed this structure for all numerical method’s numerical solutions to the smoothed dam-break problem with  $\alpha$  values as low as  $1m$  and  $\Delta x = 10/2^{11}m$ . The numerical solutions of Mitsotakis et al. [1] use  $\alpha = 1m$  but different heights and observe the structure  $\mathcal{S}_2$ . Therefore Mitsotakis et al. [1] and Mitsotakis et al. [9] observe the  $\mathcal{S}_2$

Table 1: All errors in conservation  $C_1^q$  for the conserved quantities and relative differences  $L_1^q$  of the primitive variables for numerical solutions of  $\mathcal{V}_3$ .  $L_1^q$  uses the numerical solution with  $\Delta x = 10/2^{11}m$  as the high resolution basis of comparison and  $\dagger$  indicates the omission of the interval  $[520m, 540m]$  from the comparison.

Figure 5: Numerical solutions of  $\mathcal{V}_3$  at  $t = 30s$  for the smooth dam-break problem with  $\alpha = 2m$  for  $\Delta x = 10/2^{10}m$  (—),  $10/2^8m$  (—),  $10/2^6m$  (—) and  $10/2^4m$  (—). The important quantities  $A^+$  (—),  $h_2$  (—) and  $x_{u_2}$  (···) are also presented.

Figure 6: Numerical solution of  $\mathcal{V}_1$  at  $t = 30s$  for the smooth dam-break problem with  $\alpha = 0.001m$  for  $\Delta x = 10/2^{11}m$  (—).

261 structure in their numerical results due to their choice of  $\alpha$  for the smoothed dam-break  
 262 problem.

263 The first-order method  $\mathcal{V}_1$  is diffusive [4] and damps oscillations that are present  
 264 in the numerical solutions of higher-order methods as in Figure 3. We find that for any  
 265 smoothed dam-break problem with  $\alpha \leq 4m$  and the dam-break problem only the  $\mathcal{S}_2$   
 266 structure is observed for the numerical solutions of  $\mathcal{V}_1$  at  $t = 30s$  with  $\Delta x = 10/2^{11}m$ .  
 267 This is evident in Figure 6 with the numerical solutions of  $\mathcal{V}_1$  using our finest grid  
 268 where  $\Delta x = 10/2^{11}m$  on our steepest initial conditions where  $\alpha = 0.001m$ . There-  
 269 fore, Le Métayer et al. [2] using the diffusive  $\mathcal{V}_1$  with their chosen  $\Delta x$  and  $\Delta t$ , which  
 270 are larger than our  $\Delta x$  and  $\Delta t$  could only observe the  $\mathcal{S}_2$  structure for the dam-break  
 271 problem.

### 272 5.1.3. Node Structure

273 The “node” structure,  $\mathcal{S}_3$  was observed by El et al. [8]. The  $\mathcal{S}_3$  structure has os-  
 274 cillations throughout regions III and IV that decay to a node at  $x_{u_2}$  as can be seen in

275 Figure 7 where  $\alpha = 0.4m$ .

276 Figure 7 demonstrates that our numerical solutions have not converged, however  
277 this is only in the area around  $x_{u_2}$ . Due to the large difference in numerical solutions  
278 around  $x_{u_2}$  the  $L_1$  measure over the area around  $x_{u_2}$  would not be insightful. However,  
279 by omitting this region we can gain some knowledge about how well our solutions  
280 agree away from  $x_{u_2}$ . This was performed for the relevant  $L_1$  measures in Table 1  
281 by omitting the interval  $[520m, 540m]$ . These modified  $L_1$  measures demonstrate that  
282 while our numerical results have visually converged outside this interval, they have not  
283 converged down to round-off error.

284 Table 1 demonstrates that the  $C_1$  measures are still decreasing and have only at-  
285 tained round-off error for  $h$ . Therefore, to resolve the desired convergence of the nu-  
286 merical solutions to one with small error in conservation using  $\mathcal{V}_3$  would require even  
287 smaller  $\Delta x$  values.

288 There is good agreement across different numerical methods for  $\Delta x = 10/2^{11}m$  as  
289 can be seen in Figure 8. In particular all the higher-order methods exhibit the same  
290 structure and only disagree in a very small region around  $x_{u_2}$ . We observe that the  
291 numerical solution of the worst higher-order method  $\mathcal{E}$  has not converged well to the  
292 numerical solutions of the other higher-order methods.

293 We have only obtained a good approximation to the desired numerical solution as  
294  $\Delta x \rightarrow 0$  away from  $x_{u_2}$ . However, our highest resolution numerical solutions from  
295 various higher-order methods are very similar. This suggests that again although we  
296 do not have full convergence, our highest resolution numerical solution is a good ap-  
297 proximation to the desired numerical solution over the whole domain. Therefore, our  
298 highest resolution numerical solutions are an accurate representation of the solutions of  
299 the Serre equations for this smoothed dam-break problem. Therefore, the  $\mathcal{S}_3$  structure  
300 should be observed in the solutions of the Serre equations for the smoothed dam-break  
301 problem with  $\alpha = 0.4m$ .

302 These numerical solutions support the findings of El et al. [8] who also use some  
303 smoothing [7] but do not report what smoothing was performed. Using their method  $\mathcal{E}$   
304 and similar  $\Delta x$  to El et al. [8] we observe the  $\mathcal{S}_4$  “growth” structure in the numerical  
305 solution for  $\alpha$  values smaller than  $0.1m$ , indicating that the smoothing performed by El  
306 et al. [8] limited their observed behaviour to just the  $\mathcal{S}_3$  structure.

#### 307 5.1.4. Growth Structure

308 The  $\mathcal{S}_4$  “growth” structure, which has hitherto not been commonly published in the  
309 literature features a growth in the oscillation amplitude around  $x_{u_2}$ . This growth is a  
310 result of the interaction of the left and right wave trains, which were predicted by the  
311 linear theory of Dougalis et al. [17] to be separate.

312 An example of the growth structure can be seen for  $\mathcal{V}_3$ ’s numerical solutions in  
313 Figure 9 to the smoothed dam-break problem with  $\alpha = 0.1m$ . This structure was  
314 observed in the numerical solutions of  $\mathcal{V}_3$  for  $\Delta x = 10/2^{11}m$  at  $t = 30s$  for  $\alpha$  values  
315 as low as  $0.001m$  and even for the dam-break problem. The growth structure has also  
316 been observed using the finite element method of Mitsotakis et al. [18].

317 Figure 9 shows that this structure can only be observed for  $\Delta x = 10/2^{10}m$ , with poor  
318 convergence of the numerical results around  $x_{u_2}$ . Again our  $L_1$  measures in Table 1 omit  
319 the interval  $[520m, 540m]$  in the numerical solutions. This demonstrates that although

Figure 7: Numerical solutions of  $\mathcal{V}_3$  at  $t = 30s$  for the smooth dam-break problem with  $\alpha = 0.4m$  for  $\Delta x = 10/2^{10}m$  (—),  $10/2^8m$  (—),  $10/2^6m$  (—) and  $10/2^4m$  (—). The important quantities  $A^+$  (—),  $h_2$  (—) and  $x_{u_2}$  (···) are also presented.

Figure 8: Numerical solutions of  $\mathcal{D}$  (—),  $\mathcal{E}$  (—),  $\mathcal{V}_3$  (—) and  $\mathcal{V}_2$  (—) at  $t = 30s$  with  $\Delta x = 10/2^{11}m$  for the smoothed dam-break problem with  $\alpha = 0.4m$ . The important quantities  $A^+$  (—) and  $x_{u_2}$  (····) are also presented.

we have visual convergence away from  $x_{u_2}$  our numerical solutions have not converged to round-off error as  $\Delta x \rightarrow 0$ . The  $C_1$  measures in Table 1 are still decreasing and have only attained round-off error for  $h$ , although for  $uh$  and  $\mathcal{H}$  the errors in conservation are small. These measures continue the trend in Table 1 where smaller  $\alpha$ 's and thus steeper initial conditions lead to larger  $L_1$  and  $C_1$  measures because steeper problems are more difficult to solve accurately.

Figure 10 demonstrates that our numerical solutions for  $\Delta x = 10/2^{11}m$  with the best methods  $\mathcal{D}$ ,  $\mathcal{V}_3$  and  $\mathcal{V}_2$  disagree for only a few oscillations around  $x_{u_2}$ . Since both  $\mathcal{D}$  and  $\mathcal{E}$  are second-order finite difference methods their errors are dispersive. These dispersive errors cause the numerical solutions to overestimate the oscillation amplitude of the true solution, particularly around  $x_{u_2}$ . Because the dispersive errors of  $\mathcal{E}$  are larger than  $\mathcal{D}$  more oscillations are observed for the numerical solutions produced by  $\mathcal{E}$ . The  $\mathcal{V}_3$  method was shown to be diffusive by Zoppou et al. [4] and therefore its numerical solutions underestimate the oscillation amplitude in the true solution. Therefore, the true solution of the Serre equations should be between the dispersive method  $\mathcal{D}$  and the diffusive method  $\mathcal{V}_3$ , and thus will possess the  $\mathcal{S}_4$  structure.

The numerical solutions of  $\mathcal{D}$  and  $\mathcal{V}_3$  acting as upper and lower bounds respectively for the oscillation amplitude as  $\Delta x$  is reduced is demonstrated in Figure 11 using the maximum of  $h$  in the interval  $[520m, 540m]$ . From this figure it is clear that the amplitudes of the numerical solutions of  $\mathcal{D}$  converge down to the limit as the resolution is increased while the numerical solution amplitudes of  $\mathcal{V}_3$  converge up to it. This shows that we have effectively bounded the true solution of the Serre equations. Unfortunately,  $\mathcal{V}_3$  could not be run in reasonable computational times with lower  $\Delta x$ , but the numerical solutions of  $\mathcal{D}$  show that doing so is unnecessary.

These results indicate that the solutions of the Serre equations to the smoothed dam-break problem with sufficiently small  $\alpha$  values should exhibit a growth structure at  $t = 30s$ , even though we have not precisely resolved all the oscillations in our numerical solutions.

It was found that decreasing  $\alpha$  did increase the amplitude of the oscillations around  $x_{u_2}$ . For  $\mathcal{V}_3$  with  $\Delta x = 10/2^{11}m$  and  $\alpha = 0.001m$  the oscillations in  $h$  were bounded by the interval  $[1.28m, 1.46m]$ . Of particular note is that the number of oscillations are the same in Figures 8 and 10 for the best methods even though they have different structures.

By changing the interval and desired time for the numerical solution,  $\Delta x$  could be lowered further so that by  $t = 3s$  our numerical solutions have fully converged for  $\alpha$  values as low as  $0.001m$ . This allows us to show that the height of the oscillations around  $x_{u_2}$  for the solution of the Serre equation to the smoothed dam-break problem are bounded at  $t = 3s$  as  $\alpha \rightarrow 0$ . Figure 12 demonstrates this for the numerical solutions of  $\mathcal{V}_3$  with  $\Delta x = 10/2^{13}m$ .

## 5.2. Shallow water wave equation comparison

The dispersive shock fitting method outlined in the review article of El and Hoefer [7], demonstrates that asymptotically the means of  $h$  and  $u$  inside the undular bore of the Serre equations are equal to the height and velocity inside the bore of the shallow water wave equations. This is the basis for the comparison in the literature [2, 9]

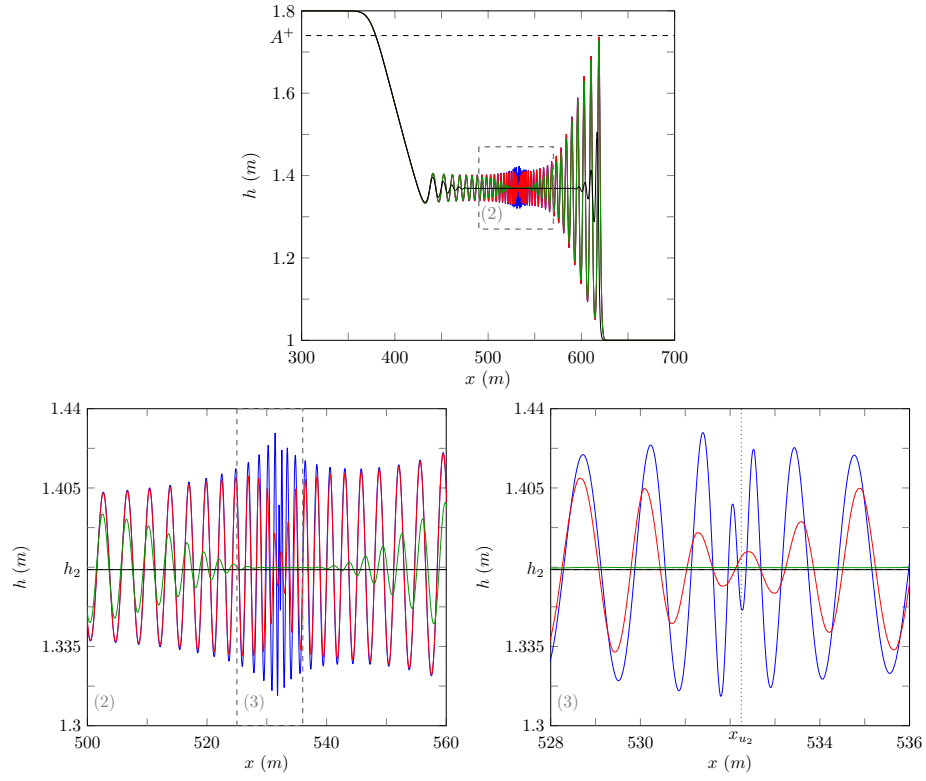

Figure 9: Numerical solutions of  $\mathcal{V}_3$  at  $t = 30s$  for the smooth dam-break problem with  $\alpha = 0.1m$  for  $\Delta x = 10/2^{10}m$  (—),  $10/2^8m$  (—),  $10/2^6m$  (—) and  $10/2^4m$  (—). The important quantities  $A^+$  (—),  $h_2$  (—) and  $x_{u_2}$  (···) are also presented.

Figure 10: Numerical solutions of  $\mathcal{D}$  (—),  $\mathcal{E}$  (—),  $\mathcal{V}_3$  (—) and  $\mathcal{V}_2$  (—) at  $t = 30s$  with  $\Delta x = 10/2^{11}m$  for the smoothed dam-break problem with  $\alpha = 0.1m$ . The important quantities  $A^+$  (—) and  $x_{u_2}$  (···) are also presented.

Figure 11: Maximum height of numerical solution of the smoothed dam-break problem with  $\alpha = 0.4m$  at  $t = 30s$  inside the interval  $[520m, 540m]$  using  $\mathcal{D}$  (□) and  $\mathcal{V}_3$  (○).

Figure 12: Maximum height of numerical solution around  $x_{u_2}$  at  $t = 3s$  of various smoothed dam-break problem as  $\alpha$  decreases, using  $\mathcal{V}_3$  ( $\square$ ) with  $\Delta x = 10/2^{13}m$ .

between the numerical solution of the Serre equations and the analytic solutions of the shallow water wave equations for the dam-break problem.

This relationship was investigated in the short term with our numerical solutions by using the mean bore depth and mean fluid velocity in the interval  $[x_{u_2} - 50m, x_{u_2} + 50m]$  from our numerical solutions to the smoothed dam-break problem with various height ratios. These means were compared to the analytical solution of the dam-break problem for the shallow water wave equations, which gives the height  $h_2$  and velocity  $u_2$  inside the bore. The results of this can be seen in Figure 13 for numerical solutions of  $\mathcal{V}_3$  with  $\Delta x = 10/2^9m$  to the smoothed dam-break problem at  $t = 100s$  with  $\alpha = 0.1m$  where  $h_0$  is fixed and  $h_1$  is varied.

We use a final time of  $t = 100s$  as it allows the internal structure of the bore to develop more fully giving a more reliable mean estimate, as a consequence we resort to a coarser grid to keep the run-times reasonable. We find that decreasing  $\Delta x$  does not significantly alter the mean of  $h$  and  $u$ . We also find that decreasing  $\alpha$  also does not significantly alter the mean of  $h$  and  $u$ . Therefore, the mean behaviour of the true solution of the Serre equations to the dam-break problem is captured by these numerical solutions, if it exists.

It can be seen that  $h_2$  and  $u_2$  are very close to the mean behaviour of the fluid inside the bore for a range of different aspect ratios. Although, as  $h_1/h_0$  increases this approximation becomes worse, so that  $h_2$  becomes an underestimate and consequently  $u_2$  is an overestimate. Most likely this is due to the increasing influence of non-linearity on the undulations.

We find that for  $h_1/h_0 = 1.8$  the mean values of  $h$  and  $u$  inside the bore for the Serre equations are not equal to  $h_2$  and  $u_2$ . This can be seen in Figure 14 for the numerical solutions of  $\mathcal{V}_3$  with  $\Delta x = 10/2^9m$  to the smoothed dam-break problem with  $\alpha = 0.1m$  at  $t = 300s$ . It can be seen that  $h_2$  is an underestimate of  $h$  and  $u_2$  is an overestimate of  $u$  although the difference between these values and the mean behaviour of the Serre equations is small and only noticeable over long time periods. This agreement is quite good given that, we are numerically solving the smoothed dam-break problem and the equality of these values is an asymptotic result.

The location of the leading wave of the Serre equations slowly diverges from the

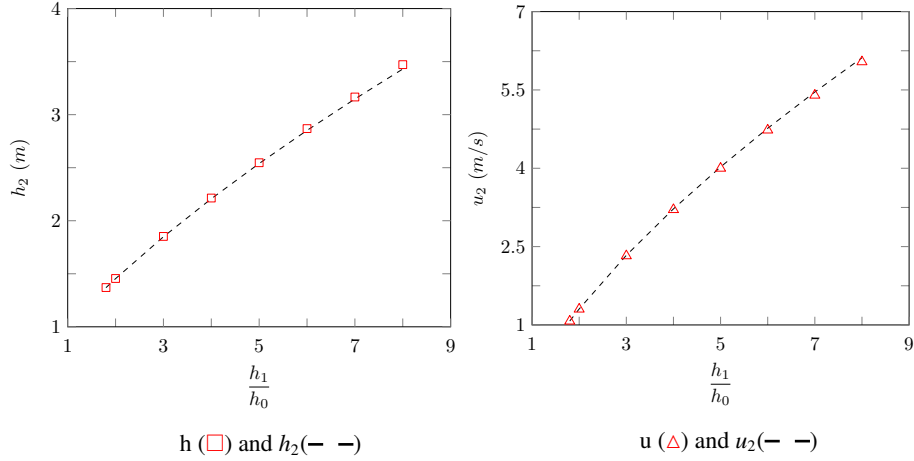

Figure 13: Comparison between mean behaviour inside the bore of the Serre equations and the analytical solution of the shallow water wave equations for a range of different aspect ratios.

location of the front of a bore in the shallow water wave equations over long periods of time. This is because the Rankine Hugoniot conditions that determine the front of the bore for the shallow water wave equations are not applicable to dispersive shock waves [7]. This divergence causes the small difference evident in  $\mathcal{V}_3$ 's numerical solution to the smoothed dam-break problem with  $\alpha = 0.1m$  at  $t = 300s$  using  $\Delta x = 10/2^9m$ , which is shown in Figure 15.

We note that the  $\mathcal{S}_4$  structure present in the numerical solutions using this method and parameters at  $t = 30s$  in Figure 9 has decayed away by  $t = 300s$  in Figure 14. This is a trend throughout our numerical solutions where oscillation amplitude decreases over time around  $x_{u_2}$ , changing the structure of the solution. This can be seen by obtaining full convergence of the numerical solutions to the smoothed dam-break problem at  $t = 3s$ . The converged to numerical solutions for  $\mathcal{V}_3$  are shown in Figure 16. From this figure it can be seen that the oscillation amplitudes for the numerical solutions for the smoothed dam-break problems with  $\alpha = 0.4m$  and  $\alpha = 0.1m$  are much larger at  $t = 3s$  than they are at  $t = 30s$  in Figure 2. Since we have demonstrated that our numerical solutions are good approximations to the true solution of the Serre equations at  $t = 30s$  and  $t = 3s$ , decreasing oscillation amplitude around  $x_{u_2}$  over time is probably a property of the Serre equations. This implies that bounding the oscillation amplitudes at time  $t = 3s$  as was done above, bounds the oscillation amplitudes at all later times.

#### 5.2.1. Contact discontinuity

El et al. [8] noted the presence of a ‘degenerate contact discontinuity’ which is where the two wave trains interact in the  $\mathcal{S}_3$  and  $\mathcal{S}_4$  structures; it travels at the mean fluid velocity in the bore.

We observe that as our numerical solutions evolve over time, oscillations appear to be released from the contact discontinuity and travel away from it in both directions, leading to a decay of amplitudes around the contact discontinuity. Therefore, the contact discontinuity is an important feature and its behaviour determines the structure of

Figure 14: The relative difference between  $h$  and  $u$  and their comparisons  $h_2$  and  $u_2$  plotted around  $x_{u_2}$  ( $\cdots$ ) for  $\mathcal{V}_3$ 's solutions with  $\Delta x = 10/2^9 m$  for the smoothed dam-break problem with  $\alpha = 0.1m$  at  $t = 300s$ .

Figure 15: Numerical solution of  $\mathcal{V}_3$  with  $\Delta x = 10/2^9 m$  for the smoothed dam-break problem with  $\alpha = 0.1m$  at  $t = 300s$  around the front of the undular bore. The important quantities  $A^+$  ( $-\ -$ ),  $x_{S_2}$  ( $-\ -$ ) and  $x_{S^+}$  ( $-\ -$ ) are also presented.

Figure 16: Numerical solution of  $\mathcal{V}_3$  with  $\Delta x = 10/2^{13} m$  for the smoothed dam-break problem with  $\alpha = 0.001m$  ( $\bullet$ ),  $0.1m$  ( $\bullet$ ) and  $0.4$  ( $\bullet$ ) at  $t = 3s$ . For comparison  $x_{u_2}$  ( $\cdots$ ) is also plotted.

Figure 17: Numerical solution of  $\mathcal{V}_3$ 's with  $\Delta x = 10/2^9 m$  for the smoothed dam-break problem with  $\alpha = 0.1m$  at  $t = 30s$  around the contact discontinuity close to  $x_{u_2}$  ( $\cdots$ ).

the oscillations in regions III and IV.

The different speeds of the oscillations are determined by the phase velocity, which for the Serre equations linearised around the mean height  $\bar{h}$  and mean velocity  $\bar{u}$  in regions III and IV is

$$v_p = \bar{u} \pm \sqrt{g\bar{h}} \sqrt{\frac{3}{\bar{h}^2 k^2 + 3}} \quad (4)$$

with wave number  $k$ . It can be seen that as  $k \rightarrow \infty$  then  $v_p \rightarrow \bar{u}$  and as  $k \rightarrow 0$  then  $v_p \rightarrow \bar{u} \pm \sqrt{g\bar{h}}$ . The left wave train corresponds to the  $-$  branch of the phase velocity while the right wave train corresponds to the  $+$  branch of the phase velocity. The contact discontinuity corresponds to the high wave-number limit of these two wave trains. Because the two wave trains correspond to the  $-$  and  $+$  branches of the phase velocity for the left wave train  $h$  and  $u$  are in-phase, while for the right wave train  $h$  and  $u$  are out-of-phase. This can be seen in Figure 17 for the numerical solutions of  $\mathcal{V}_3$  with  $\Delta x = 10/2^9 m$  for the smoothed dam-break problem with  $\alpha = 0.1m$  at  $t = 30s$ .

The  $+$  branch of the phase velocity is strictly increasing in  $k$ , while the  $-$  branch is strictly decreasing. It can also be shown that  $+$  branch and  $-$  branch of the group velocity behave in the same way with the same limits as their phase velocity counterparts. Therefore as in Dougalis et al. [17] the linear theory predicts separate dispersive wave trains. However, we have demonstrated that in the short term these wave trains are not separate and so the interaction of these wave trains in the  $\mathcal{S}_3$  and  $\mathcal{S}_4$  structures is caused by non-linear effects.

### 5.3. Whitham Modulation Comparison

El et al. [8] demonstrated that their Whitham modulation results approximated the numerical solutions of the smoothed dam-break problem well for a range of aspect ratios. We observed that the Whitham modulation results are an underestimate compared to our numerical solutions.

This can be seen in Figure 18 as the relative difference between  $A^+$  from El et al. [8] and the leading wave amplitude of our numerical solution  $A$  does not converge to 0 over

Figure 18: Relative difference between Whitham modulation result  $A^+$  and the leading wave amplitude  $A$  from our numerical solutions of  $\mathcal{V}_3$  with  $\Delta x = 10/2^9 m$  for the smoothed dam-break problem with  $\alpha = 0.1m$  over time.

time. Since we find that the numerical solutions for the smoothed dam-break problem with  $\alpha = 0.1m$  have converged for the front of the undular bore by  $\Delta x = 10/2^8 m$  as in Figure 9, our numerical solutions for  $A$  are considered reliable. We also note that unlike the oscillations around  $x_{u_2}$  the leading wave amplitude increases over time.

The Whitham modulation results for the location of the leading wave  $x_{S^+}$  is a better approximation than that given by the shallow water wave equations  $x_{S_2}$ , as can be seen in Figure 15. This is due to the inapplicability of the Rankine Hugoniot conditions from which  $S_2$  is derived for dispersive shock waves [7].

The agreement between the Whitham modulation results and our numerical solutions is actually quite good given that the Whitham modulations results are an asymptotic solution to the dam-break problem. We include them here as a counter point to the results of El et al. [8] and Mitsotakis et al. [9], as from their results one would expect that numerical solutions should only ever underestimate  $A^+$  and  $S^+$  when the ratio  $h_1/h_0$  is less than the critical value 1.94.

## 6. Conclusions

Utilising two finite difference methods of second-order and three finite difference finite volume methods of various orders to solve the nonlinear weakly dispersive Serre equations an investigation into the smoothed dam-break problem with varying steepness was performed. Four different structures of the numerical solutions were observed and demonstrated to be valid, the general trend of these structures is that an increase in steepness increases the size and number of oscillations in the solution. This study explains the different structures exhibited by the numerical results in the literature for the smoothed dam-break problem for the Serre equations and uncovers a new result. These results demonstrate that other methods in the literature could replicate our results if their simulations are extended. Furthermore, these results suggest that this new result and its associated structure is to be expected for the solution of the Serre equation to the dam-break problem at least for short enough time spans, if it exists.

We confirm that the analytical solution of the shallow water wave equations for the dam-break problem provides a reasonable approximation to the mean height and veloc-

ity inside the bore formed by the smoothed dam-break problem for the Serre equations across a range of aspect ratios. Finally, we observe that the Whitham modulations results for the leading wave of an undular bore can underestimate the leading wave amplitude and speed when the aspect ratio is below the critical value.

## 529 Appendix A.

530 The methods  $\mathcal{E}$  and  $\mathcal{D}$  use the centred second-order finite difference approximation  
 531 to the momentum equation (1b), denoted as  $\mathcal{D}_u$ . For the mass equation (1a)  $\mathcal{E}$  uses the  
 532 two step Lax-Wendroff method, denoted as  $\mathcal{E}_h$  while  $\mathcal{D}$  uses a centred second-order  
 533 finite difference approximation, denoted as  $\mathcal{D}_h$ .

### 534 Appendix A.1. $\mathcal{D}_u$ for the Momentum Equation

535 First (1b) is expanded to get

$$536 \quad h \frac{\partial u}{\partial t} - h^2 \frac{\partial^2 u}{\partial x \partial t} - \frac{h^3}{3} \frac{\partial^3 u}{\partial x^2 \partial t} = -X$$

538 where  $X$  contains only spatial derivatives and is

$$539 \quad X = uh \frac{\partial u}{\partial x} + gh \frac{\partial h}{\partial x} + h^2 \frac{\partial u}{\partial x} \frac{\partial u}{\partial x} + \frac{h^3}{3} \frac{\partial u}{\partial x} \frac{\partial^2 u}{\partial x^2} - h^2 u \frac{\partial^2 u}{\partial x^2} - \frac{h^3}{3} u \frac{\partial^3 u}{\partial x^3}.$$

541 All derivatives are approximated by second-order centred finite difference approxi-  
 542 mations on a uniform grid in space and time, which after rearranging into an update  
 543 formula becomes

$$544 \quad h_i^n u_i^{n+1} - (h_i^n)^2 \left( \frac{u_{i+1}^{n+1} - u_{i-1}^{n+1}}{2\Delta x} \right) - \frac{(h_i^n)^3}{3} \left( \frac{u_{i+1}^{n+1} - 2u_i^{n+1} + u_{i-1}^{n+1}}{\Delta x^2} \right) = -Y_i^n \quad (\text{A.1})$$

546 where

$$547 \quad Y_i^n = 2\Delta t X_i^n - h_i^n u_i^{n-1} + (h_i^n)^2 \left( \frac{u_{i+1}^{n-1} - u_{i-1}^{n-1}}{2\Delta x} \right) + \frac{(h_i^n)^3}{3} \left( \frac{u_{i+1}^{n-1} - 2u_i^{n-1} + u_{i-1}^{n-1}}{\Delta x^2} \right)$$

549 and

$$550 \quad X_i^n = u_i^n h_i^n \frac{u_{i+1}^n - u_{i-1}^n}{2\Delta x} + gh_i^n \frac{h_{i+1}^n - h_{i-1}^n}{2\Delta x} + (h_i^n)^2 \left( \frac{u_{i+1}^n - u_{i-1}^n}{2\Delta x} \right)^2$$

$$551 \quad + \frac{(h_i^n)^3}{3} \frac{u_{i+1}^n - u_{i-1}^n}{2\Delta x} \frac{u_{i+1}^n - 2u_i^n + u_{i-1}^n}{\Delta x^2} - (h_i^n)^2 u_i^n \frac{u_{i+1}^n - 2u_i^n + u_{i-1}^n}{\Delta x^2}$$

$$552 \quad - \frac{(h_i^n)^3}{3} u_i^n \frac{u_{i+2}^n - 2u_{i+1}^n + 2u_{i-1}^n - u_{i-2}^n}{2\Delta x^3}.$$

553 Equation (A.1) can be rearranged into an explicit update scheme  $\mathcal{D}_u$  for  $u$  given its  
 554 current and previous values, so that

$$557 \quad \begin{bmatrix} u_0^{n+1} \\ \vdots \\ u_m^{n+1} \end{bmatrix} = A^{-1} \begin{bmatrix} -Y_0^n \\ \vdots \\ -Y_m^n \end{bmatrix} =: \mathcal{D}_u(\mathbf{u}^n, \mathbf{h}^n, \mathbf{u}^{n-1}, \Delta x, \Delta t) \quad (\text{A.2})$$

559 where  $A$  is a tri-diagonal matrix.

560 *Appendix A.2. Numerical Methods for the Mass Equation*

561 The two step Lax-Wendroff update  $\mathcal{E}_h$  for  $h$  is

$$562 \quad h_{i+1/2}^{n+1/2} = \frac{1}{2} (h_{i+1}^n + h_i^n) - \frac{\Delta t}{2\Delta x} (u_{i+1}^n h_{i+1}^n - h_i^n u_i^n),$$

563

564

$$565 \quad h_{i-1/2}^{n+1/2} = \frac{1}{2} (h_i^n + h_{i-1}^n) - \frac{\Delta t}{2\Delta x} (u_i^n h_i^n - h_{i-1}^n u_{i-1}^n)$$

566

567 and

$$568 \quad h_i^{n+1} = h_i^n - \frac{\Delta t}{\Delta x} (u_{i+1/2}^{n+1/2} h_{i+1/2}^{n+1/2} - u_{i-1/2}^{n+1/2} h_{i-1/2}^{n+1/2}).$$

569

570 The quantities  $u_{i\pm 1/2}^{n+1/2}$  are calculated using  $u^{n+1}$  obtained by applying  $\mathcal{D}_u$  (A.2) to  $u^n$   
 571 then linearly interpolating in space and time to give

$$572 \quad u_{i+1/2}^{n+1/2} = \frac{u_{i+1}^{n+1} + u_{i+1}^n + u_i^{n+1} + u_i^n}{4}$$

573

574 and

$$575 \quad u_{i-1/2}^{n+1/2} = \frac{u_i^{n+1} + u_i^n + u_{i-1}^{n+1} + u_{i-1}^n}{4}.$$

576

577 Thus we have the following update scheme  $\mathcal{E}_h$  for (1a)

$$578 \quad \mathbf{h}^{n+1} = \mathcal{E}_h(\mathbf{u}^n, \mathbf{h}^n, \mathbf{u}^{n+1}, \Delta x, \Delta t). \quad (\text{A.3})$$

579

580 The second order centered finite difference approximation to the conservation of  
 581 mass equation (1a) is

$$582 \quad h_i^{n+1} = h_i^{n-1} - \Delta t \left( u_i^n \frac{h_{i+1}^n - h_{i-1}^n}{\Delta x} + h_i^n \frac{u_{i+1}^n - u_{i-1}^n}{\Delta x} \right).$$

583

584 Thus we have an update scheme  $\mathcal{D}_h$  for all  $i$

$$585 \quad \mathbf{h}^{n+1} = \mathcal{D}_h(\mathbf{u}^n, \mathbf{h}^n, \mathbf{h}^{n-1}, \Delta x, \Delta t). \quad (\text{A.4})$$

586

587 *Appendix A.3. Complete Method*

588 The method  $\mathcal{E}$  is the combination of (A.3) for (1a) and (A.2) for (1b) in the follow-  
 589 ing way

$$590 \quad \left. \begin{aligned} \mathbf{u}^{n+1} &= \mathcal{D}_u(\mathbf{u}^n, \mathbf{h}^n, \mathbf{u}^{n-1}, \Delta x, \Delta t) \\ \mathbf{h}^{n+1} &= \mathcal{E}_h(\mathbf{u}^n, \mathbf{h}^n, \mathbf{u}^{n+1}, \Delta x, \Delta t) \end{aligned} \right\} \mathcal{E}(\mathbf{u}^n, \mathbf{h}^n, \mathbf{u}^{n-1}, \mathbf{h}^{n-1}, \Delta x, \Delta t). \quad (\text{A.5})$$

591

592 The method  $\mathcal{D}$  is the combination of (A.4) for (1a) and (A.2) for (1b) in the follow-  
 593 ing way

$$594 \quad \left. \begin{aligned} \mathbf{h}^{n+1} &= \mathcal{D}_h(\mathbf{u}^n, \mathbf{h}^n, \mathbf{h}^{n-1}, \Delta x, \Delta t) \\ \mathbf{u}^{n+1} &= \mathcal{D}_u(\mathbf{u}^n, \mathbf{h}^n, \mathbf{u}^{n-1}, \Delta x, \Delta t) \end{aligned} \right\} \mathcal{D}(\mathbf{u}^n, \mathbf{h}^n, \mathbf{u}^{n-1}, \mathbf{h}^{n-1}, \Delta x, \Delta t). \quad (\text{A.6})$$

595
